

Improvement of pre-sowing treatments for dormant, European beech seeds

„International Conference of the European Seed kilns“

June 04-07, 2013, Bernkastel-Kues, Germany

Introduction

European beech (*Fagus sylvatica* L.)

6.7 % of forests (1/3 of optimum = 18%)

Full crops in long periods (6-10 years), weak local crops

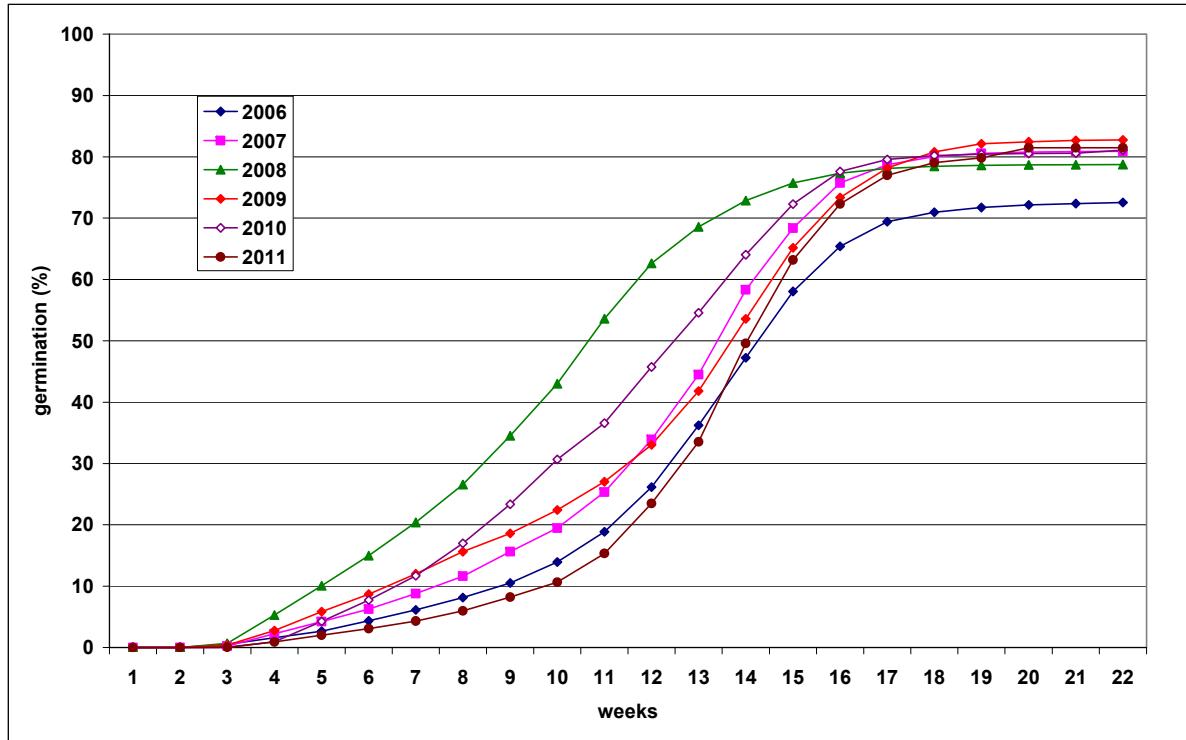

Annual demand 56 tons of seeds
30 mil. seedlings

Seed price is growing (28 EUR / kg of seeds with 100 % purity + germination)

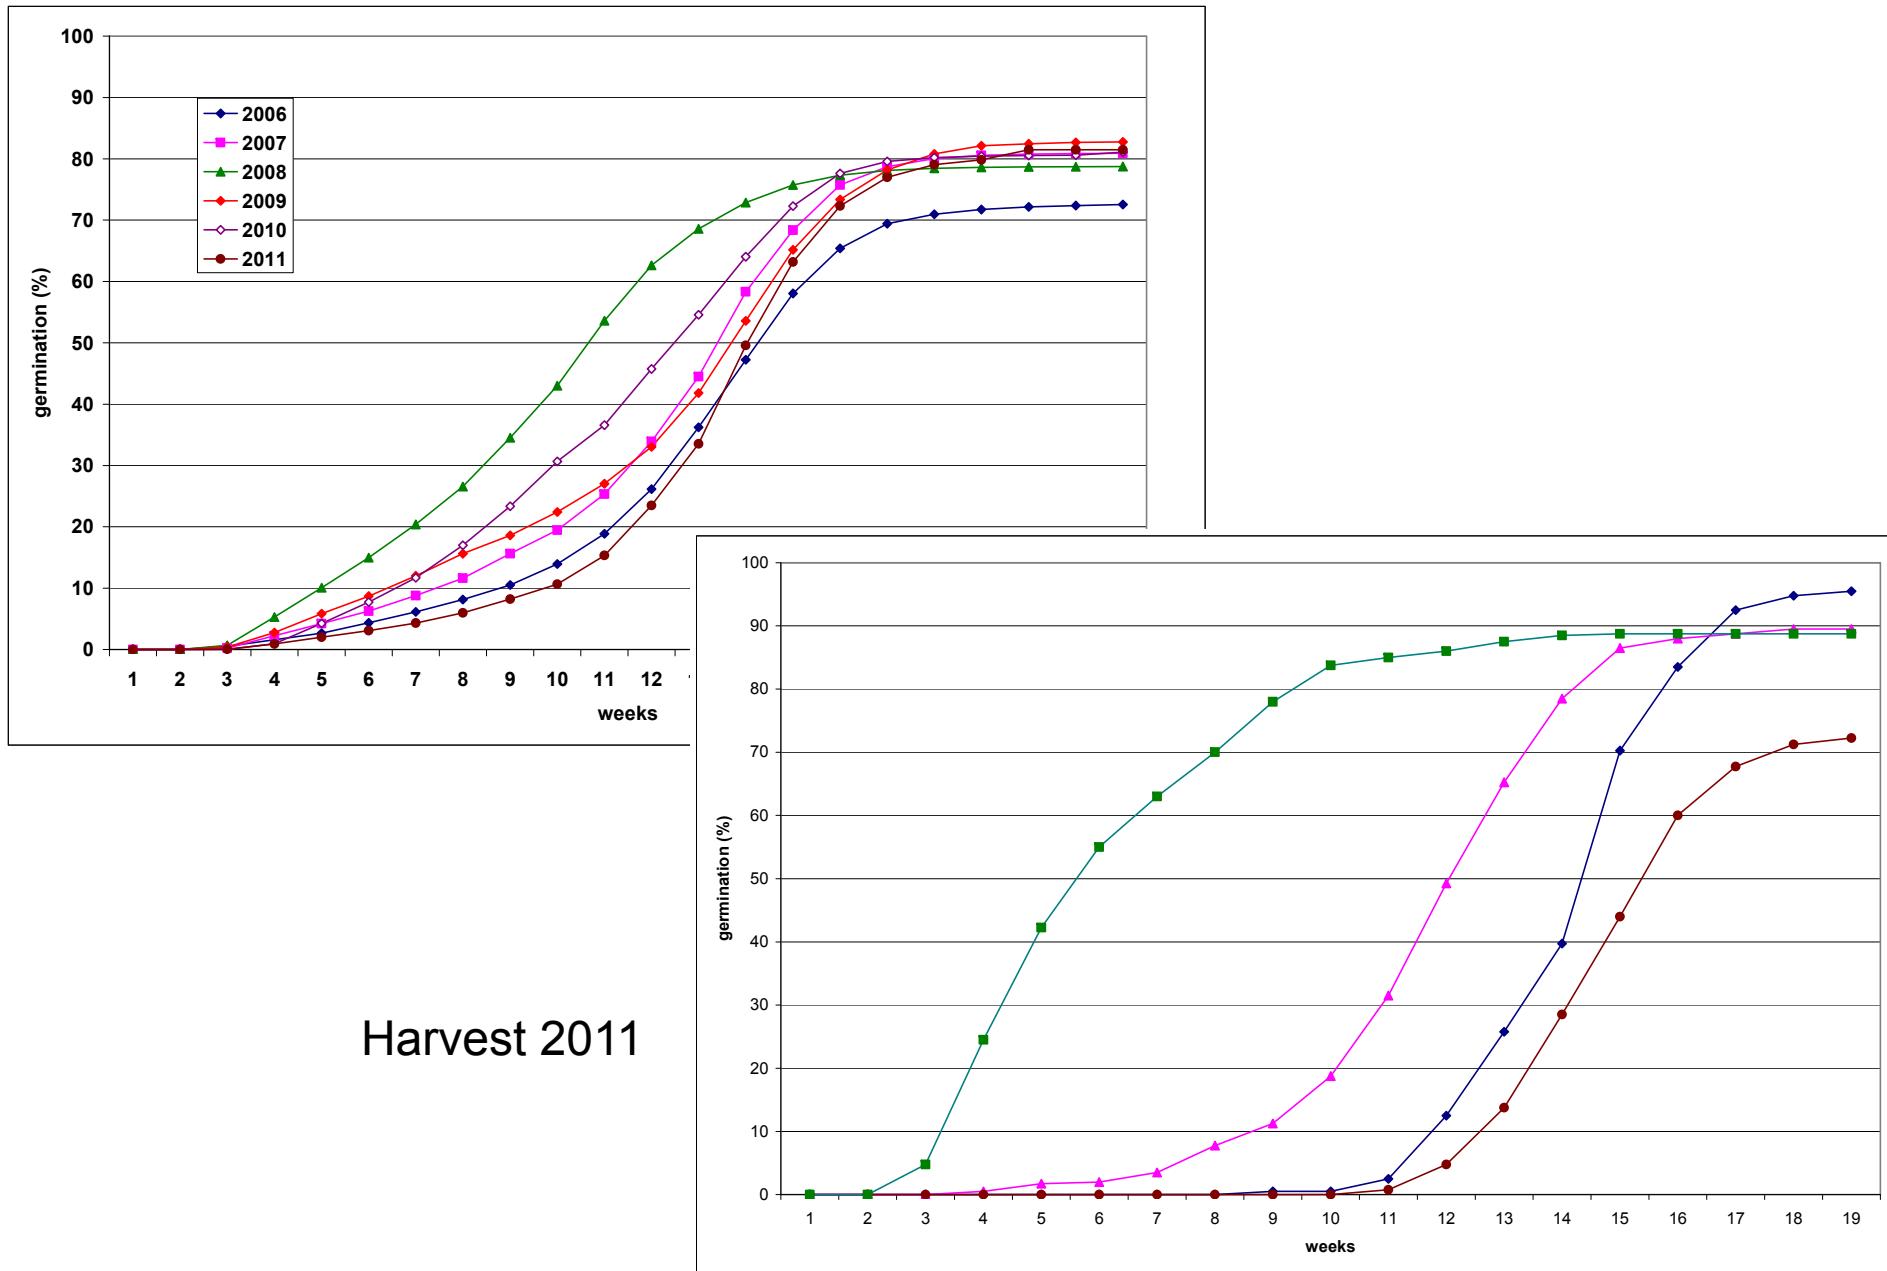

2 700 viable beechnuts / kg (ČSN 48 1211, 2006)

250 beech seedlings / kg of seed

Germination of beechnuts harvested in different years

Germination of beechnuts harvested in different years

Project QI102A256

Improvement of pre-sowing treatments for dormant, European beech seeds

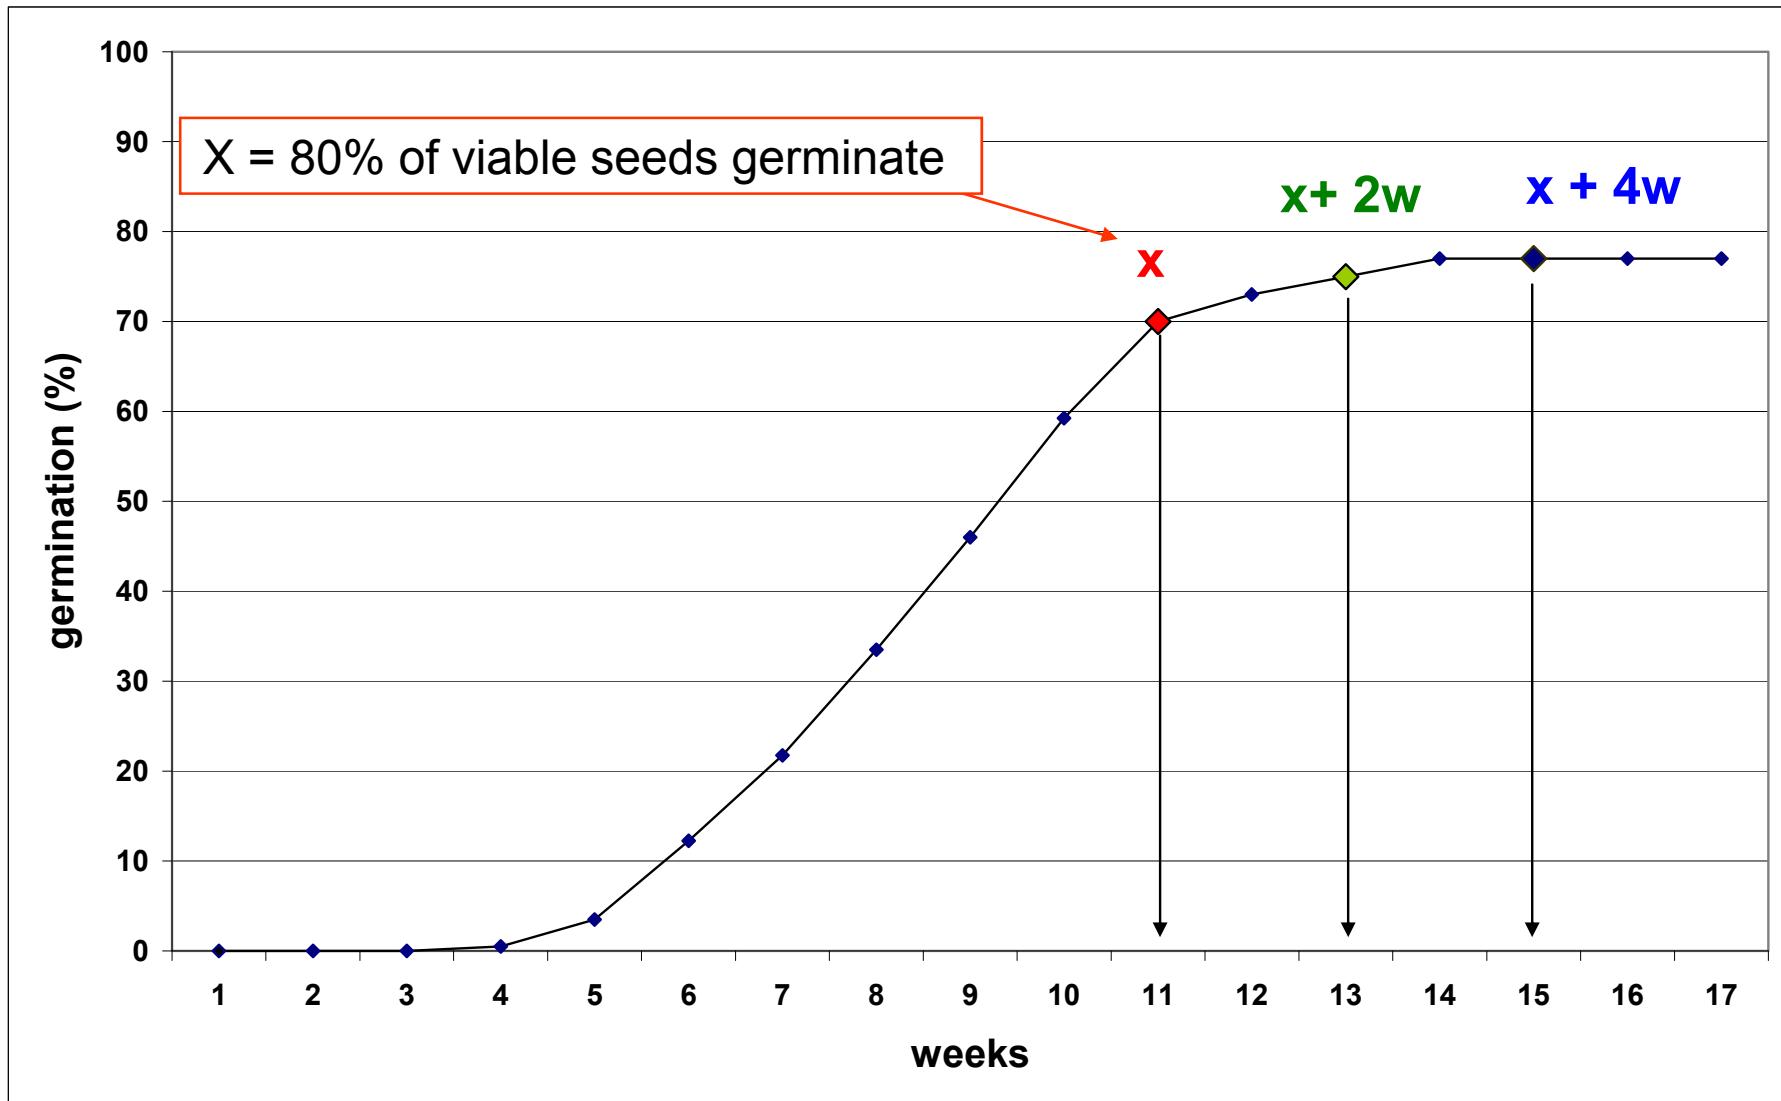

Objective

Determine factors causing low efficiency of
pre-sowing treatment of European beech
seeds (beechnuts) in the Czech republic

Determine

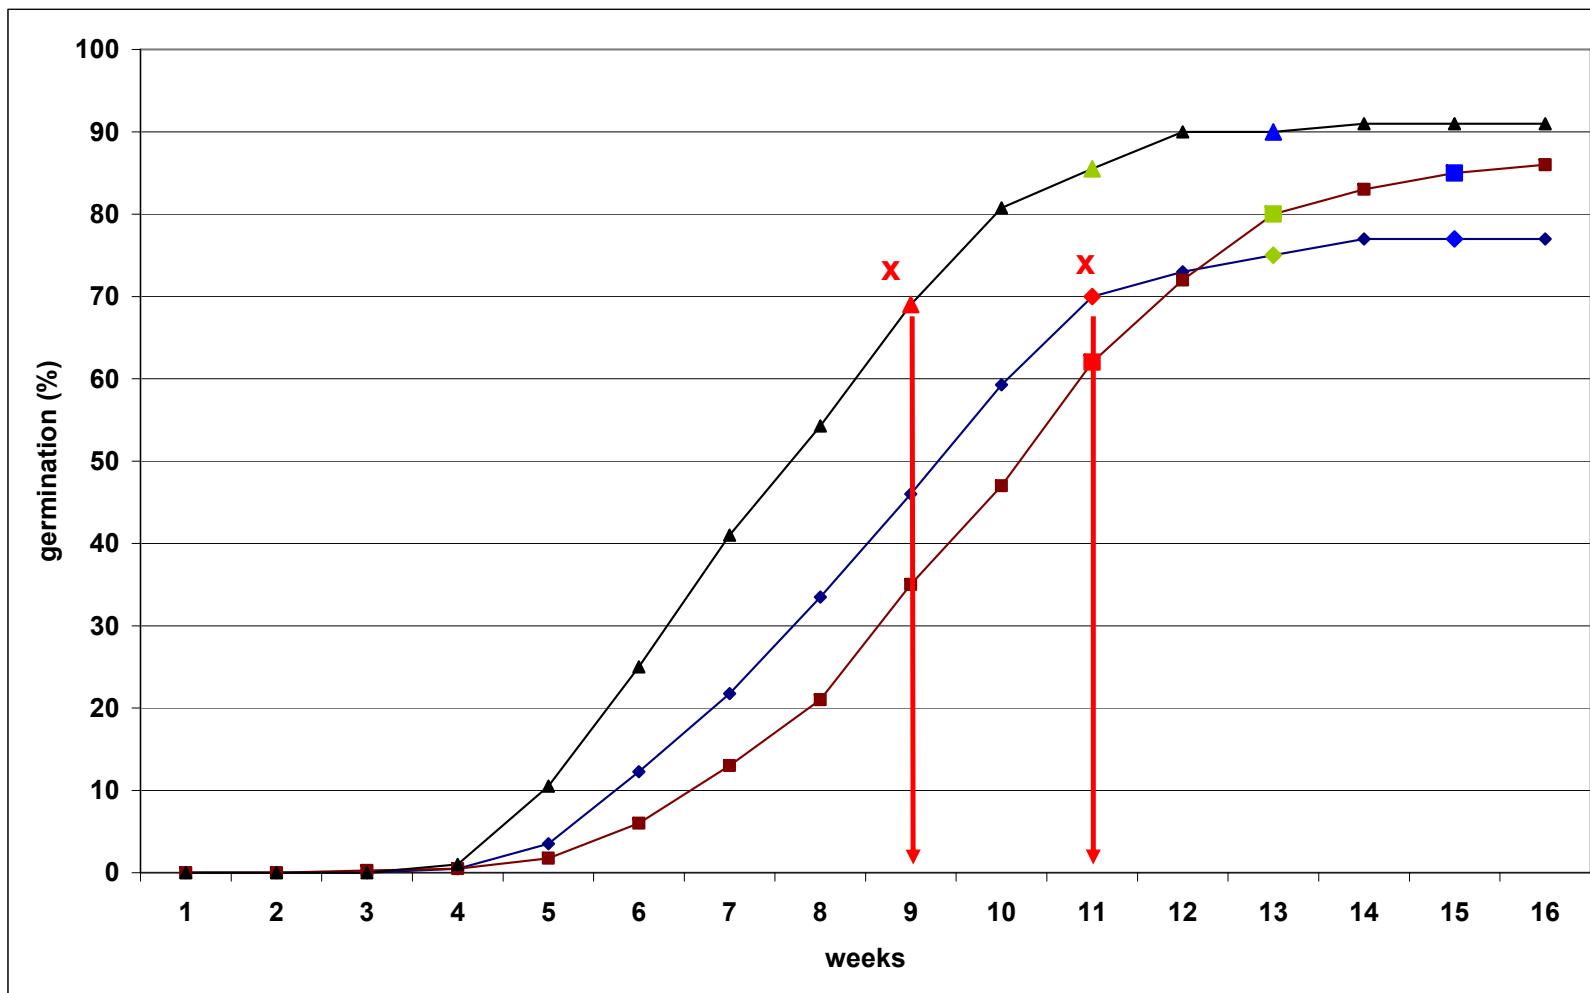

- 1) pre-chilling period of beechnuts (with various dormancy level) before storage**
- 2) effect of harvest area size on germination (capacity and rate) of beechnuts**
- 3) seasonal changes in viability, germination capacity and germination rate**
- 4) relation between ABA content, dormancy level and anatomical structure of beechnuts**

Pre-chilling of beechnuts (with various dormancy level) before storage

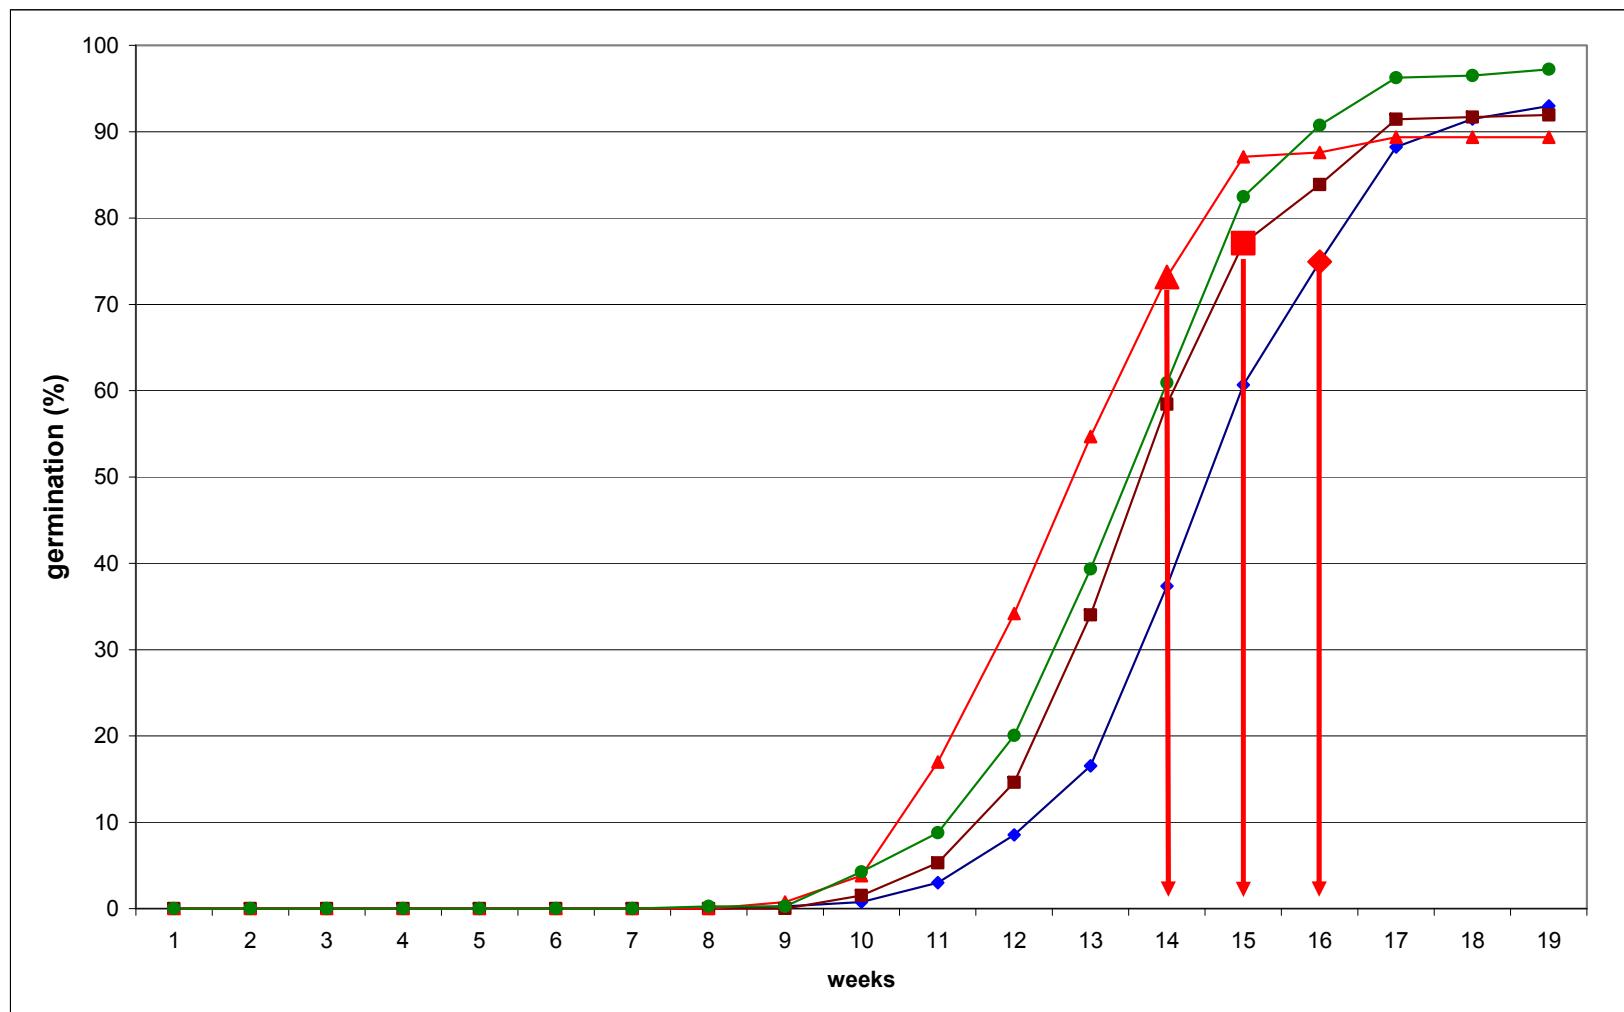

Different dormancy – harvest 2010

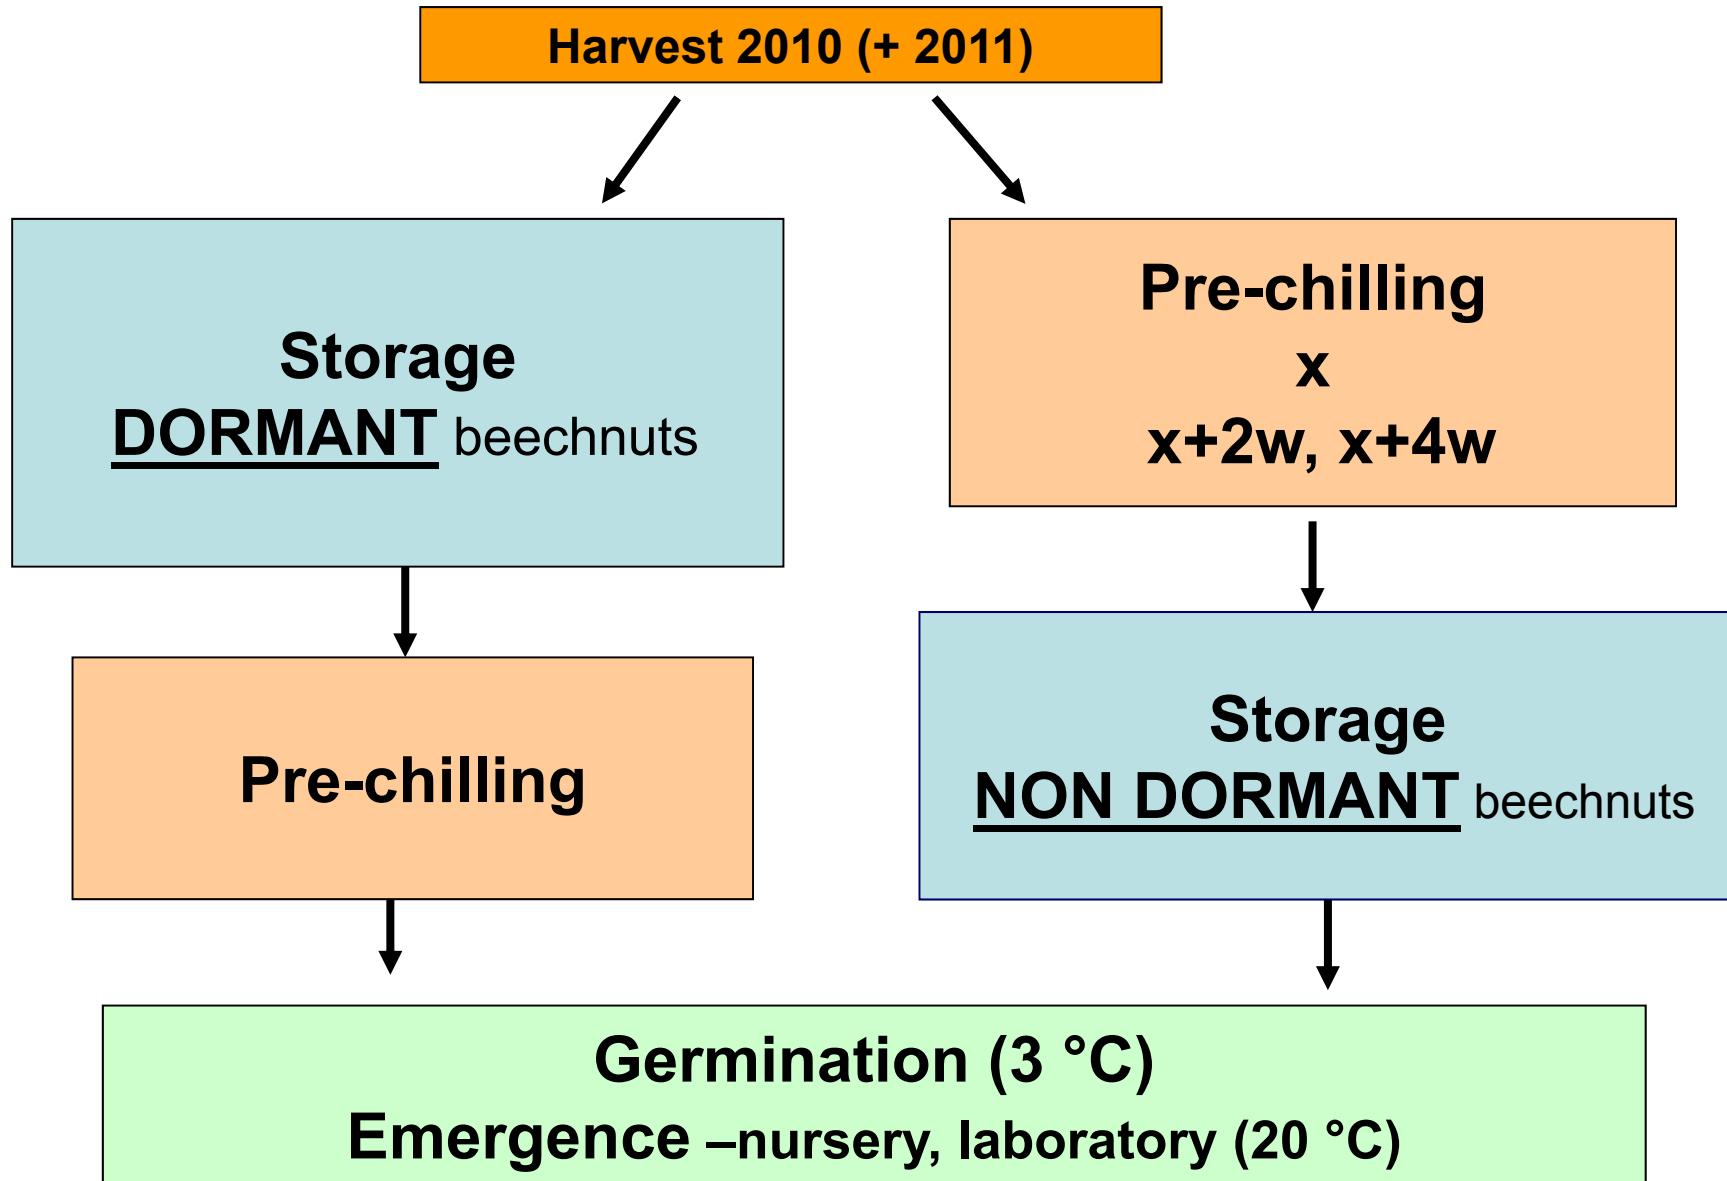

$x = 9 / 11$ weeks

Different dormancy – harvest 2011

$x = 14 / 15 / 16$ weeks („deeper“ dormancy)

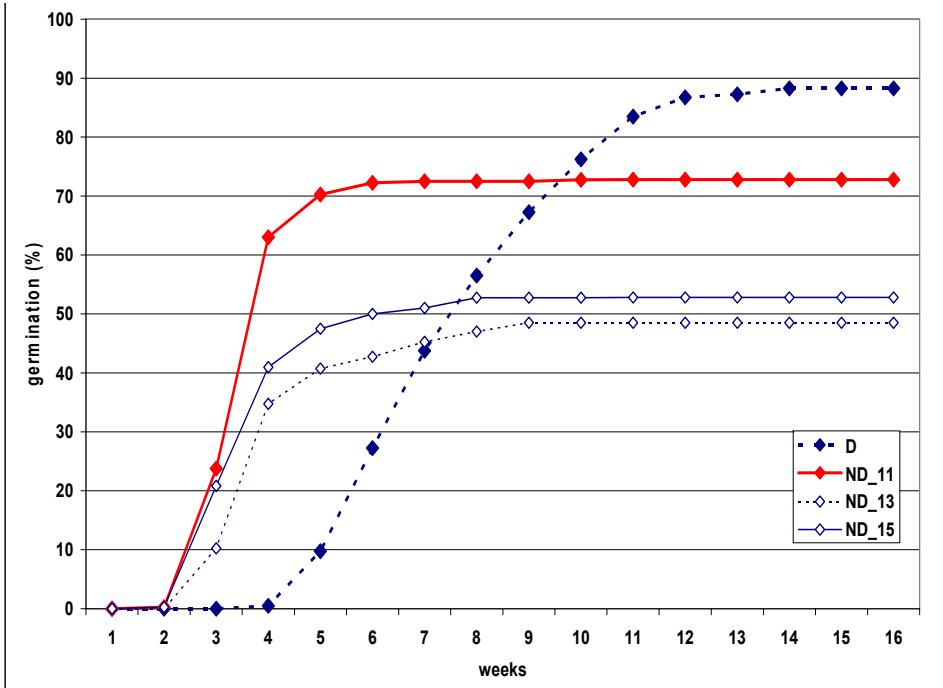

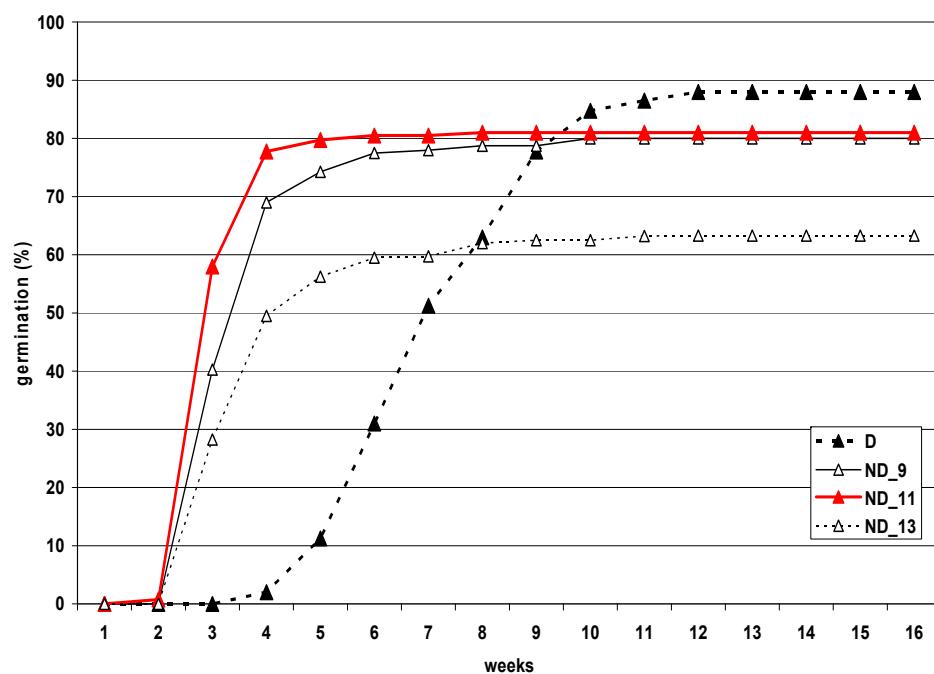

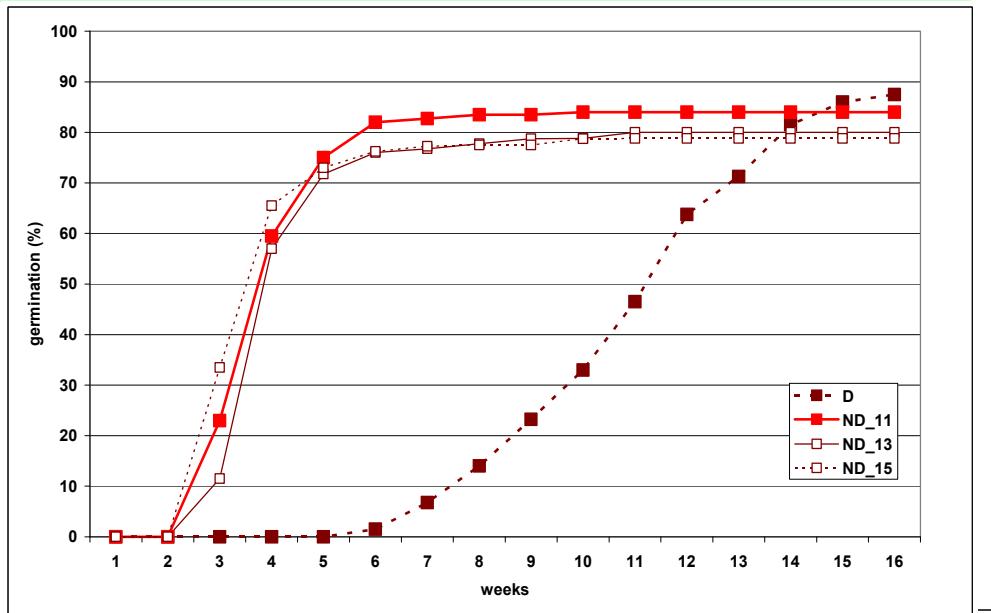

Germination at 3 °C

Harvest 2010

Dormant stored 7 m

Non dormant stored 3.5-5 m

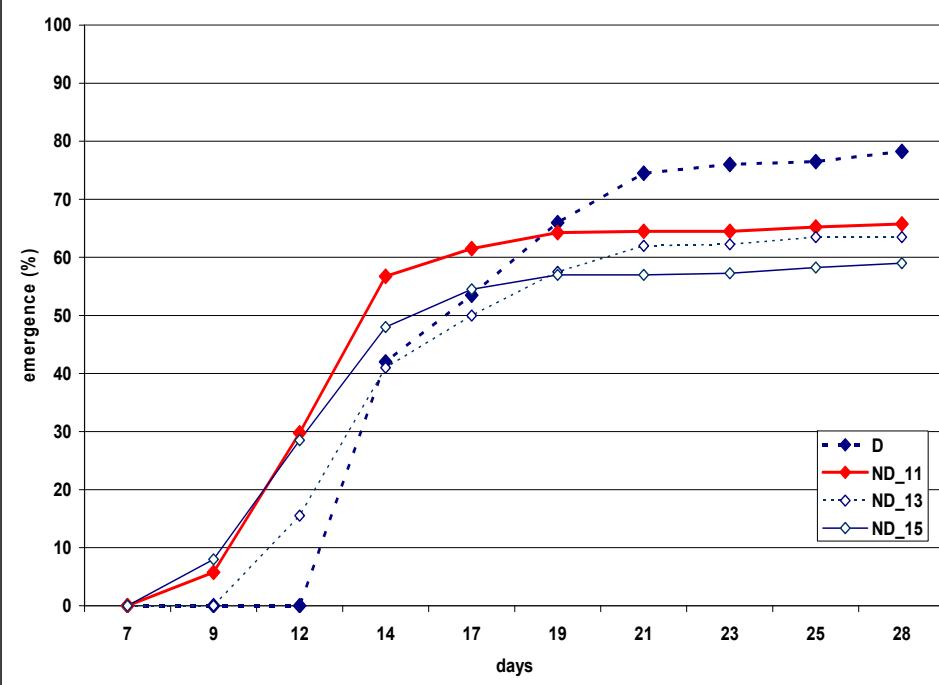

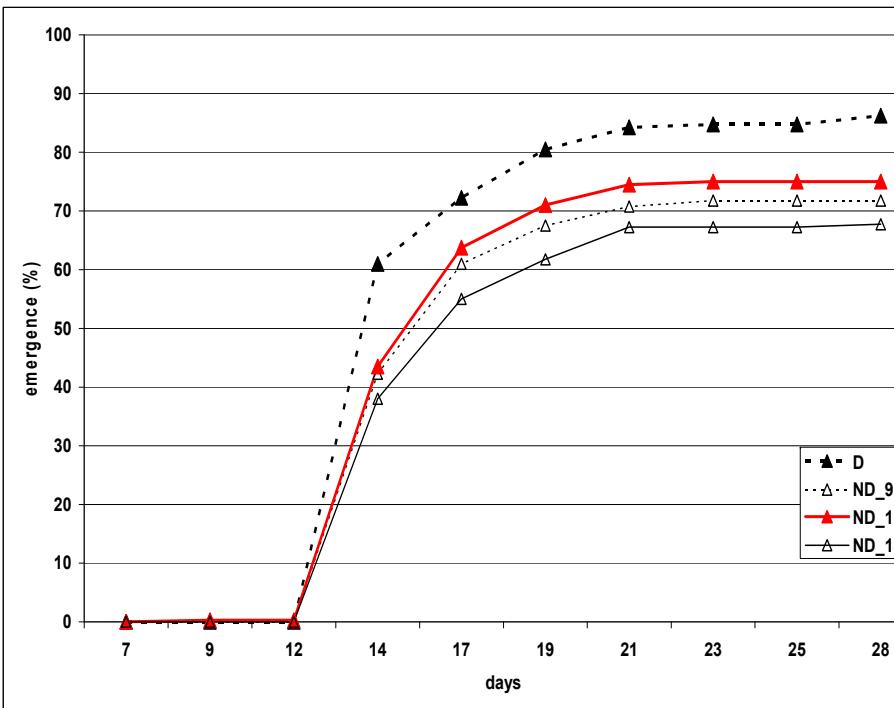

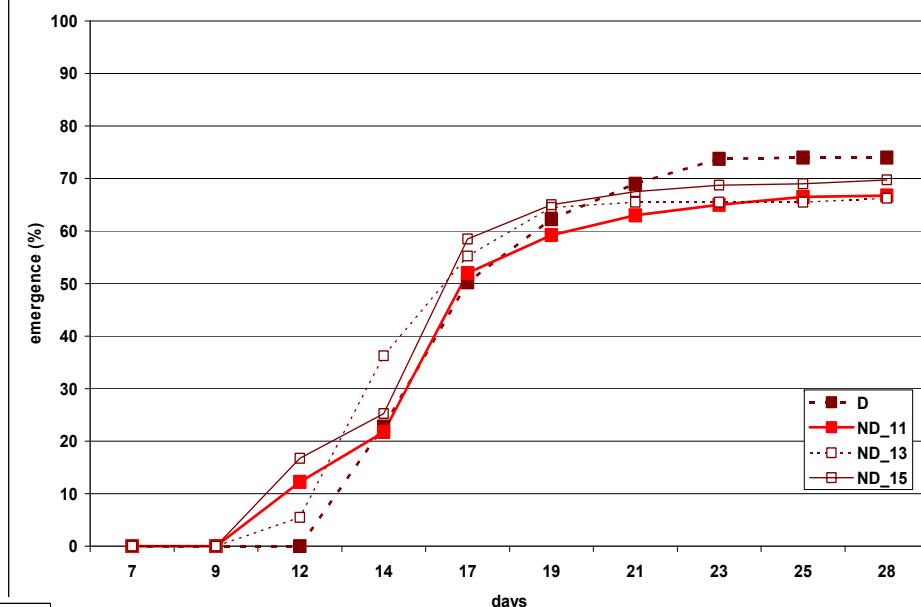

Emergence at 20 °C

Harvest 2010

Dormant stored 7 m

Non dormant stored 3.5-5 m

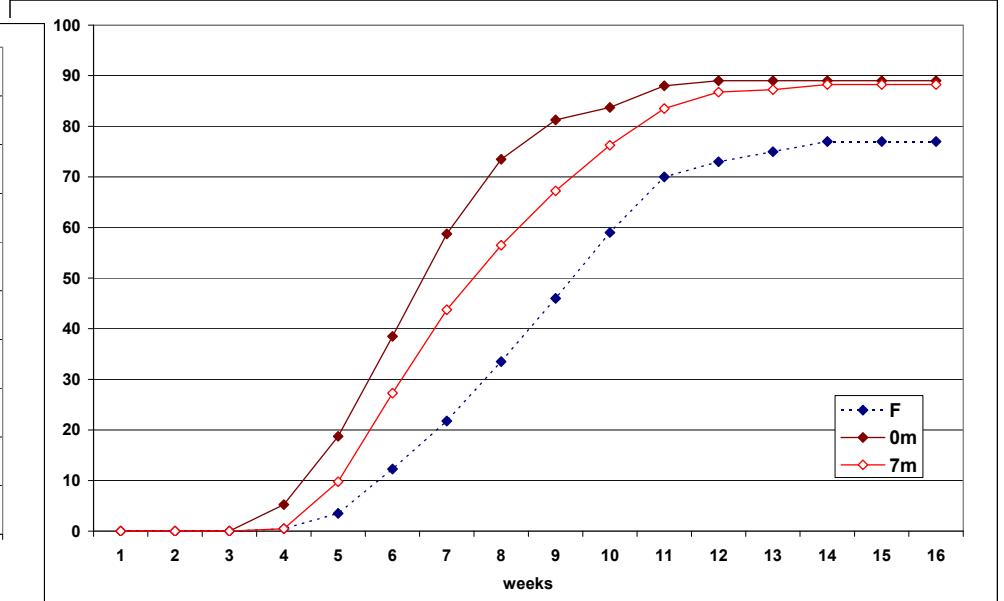

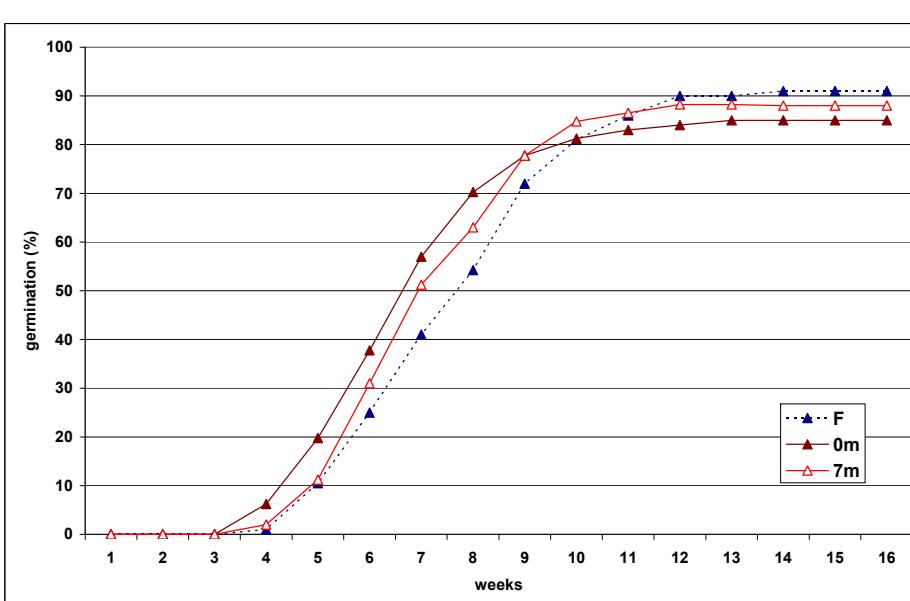

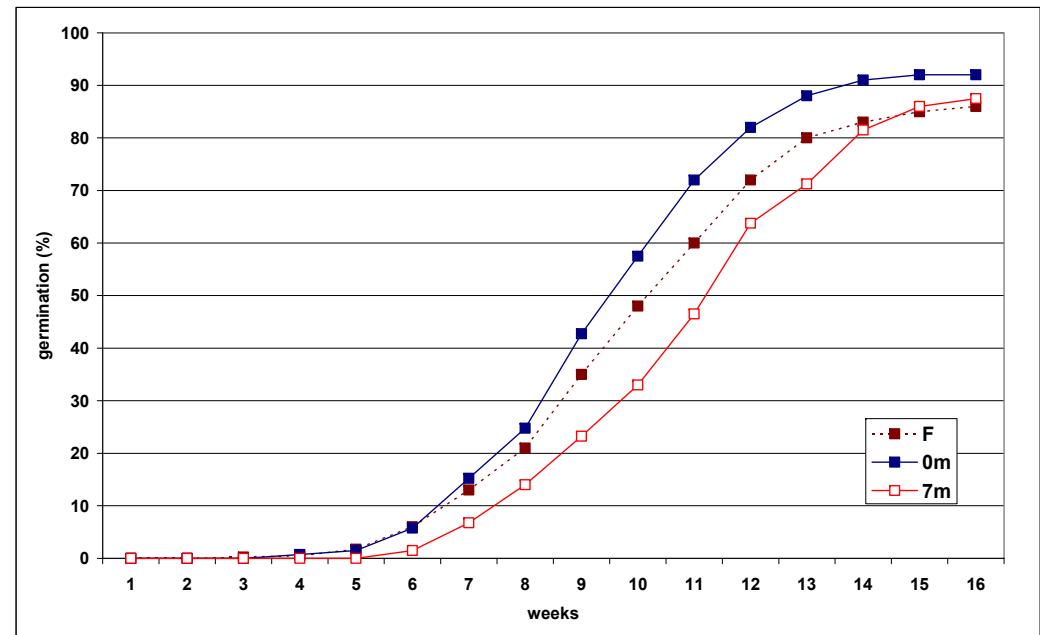

Germination at 3 °C

Harvest 2010

Dormant Fresh (no storage)

Dormant stored 0 m, 7 m
(10% MC)

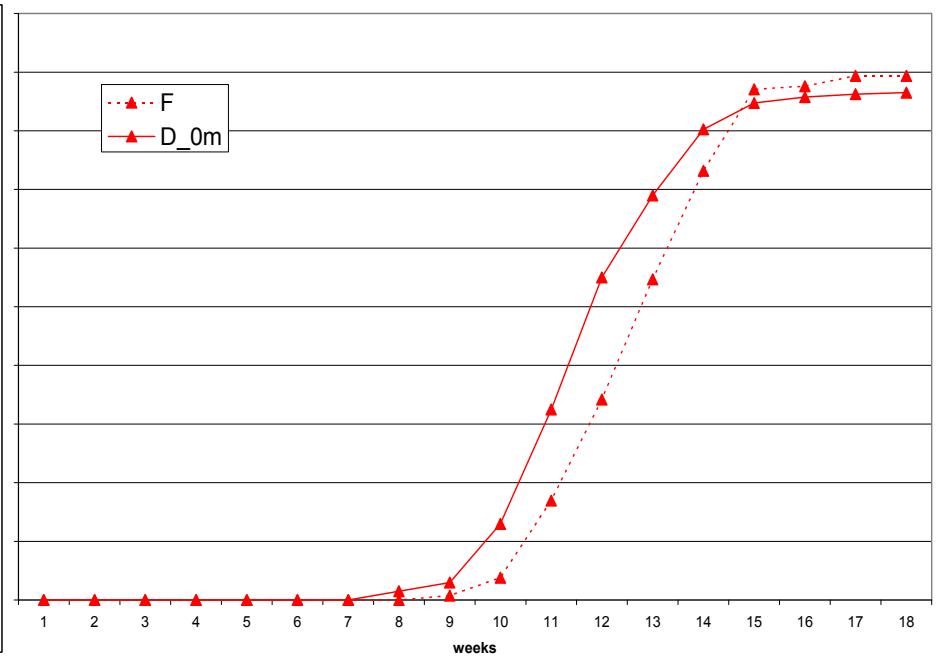

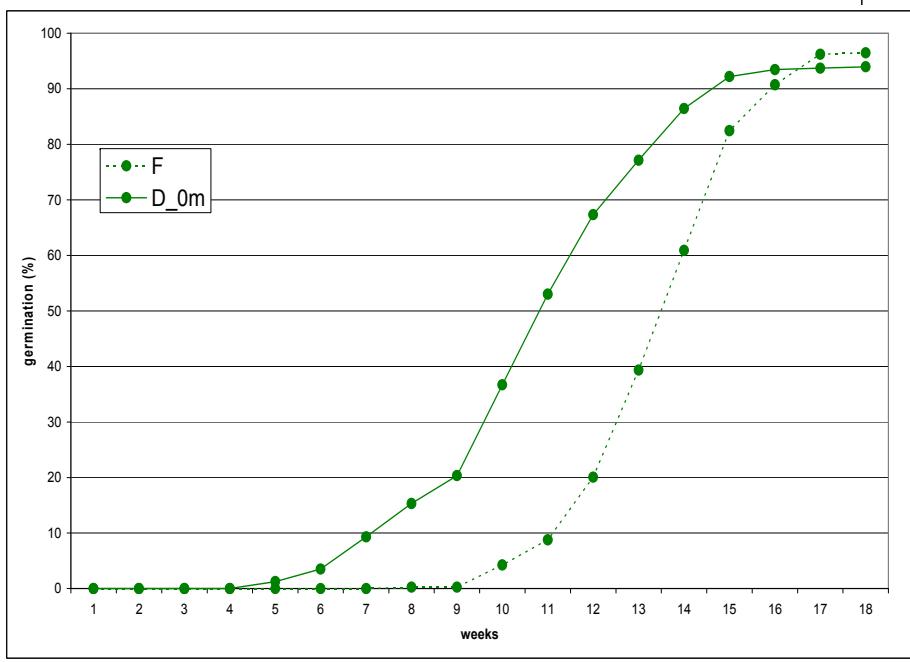

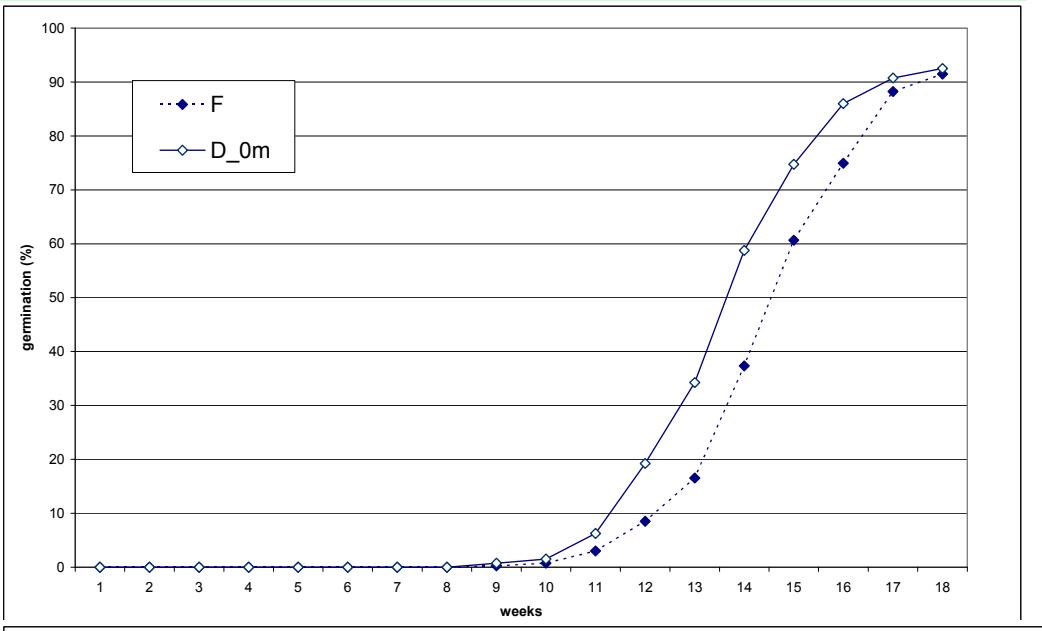

Germination at 3 °C

Harvest 2011

Dormant Fresh (no storage)

Dormant Dried stored 0 m

Conclusion

Pre-chilling after harvest varies by crop / seed lots

Drying speeds up germination by few weeks

Storage slows down germination

Seasonal changes in viability, germination capacity and germination rate

Material and methods

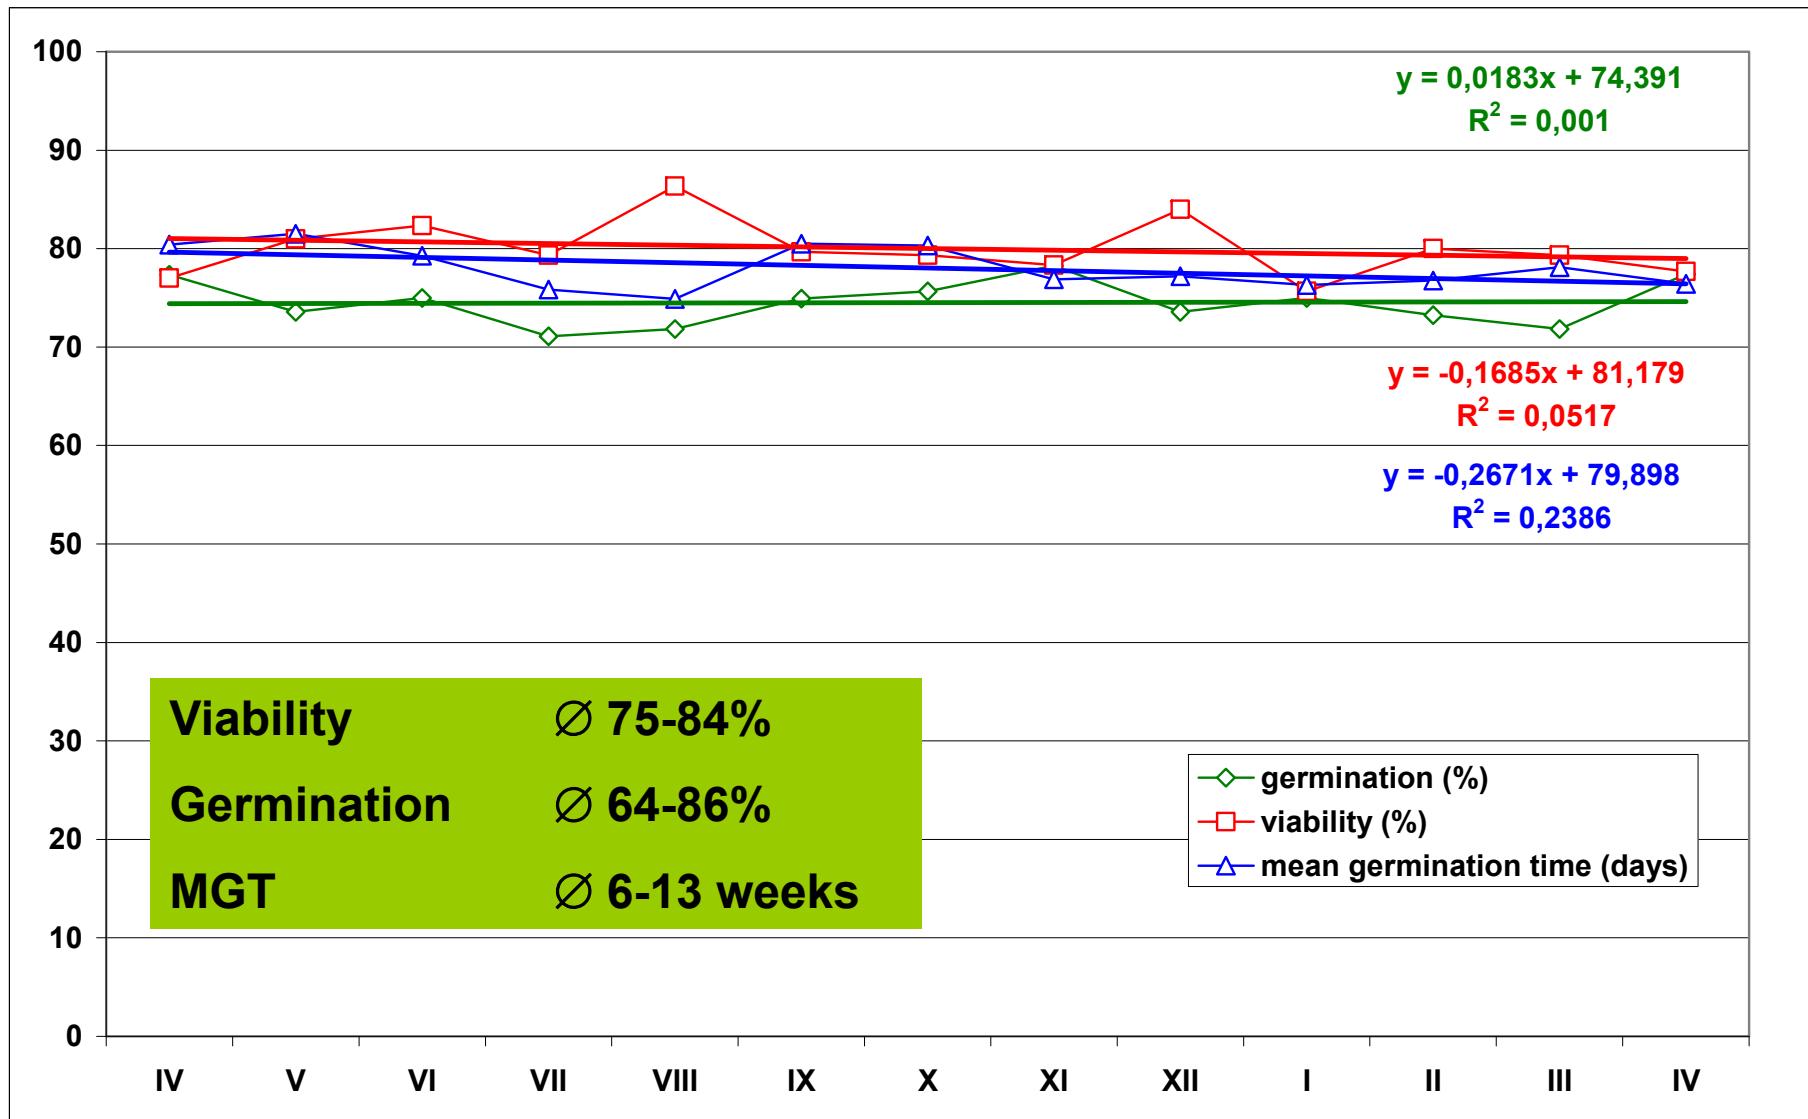

6 seed lots (crop 2009, 2010)

High, medium, low quality (viability + germination)

Viability and germination determined monthly

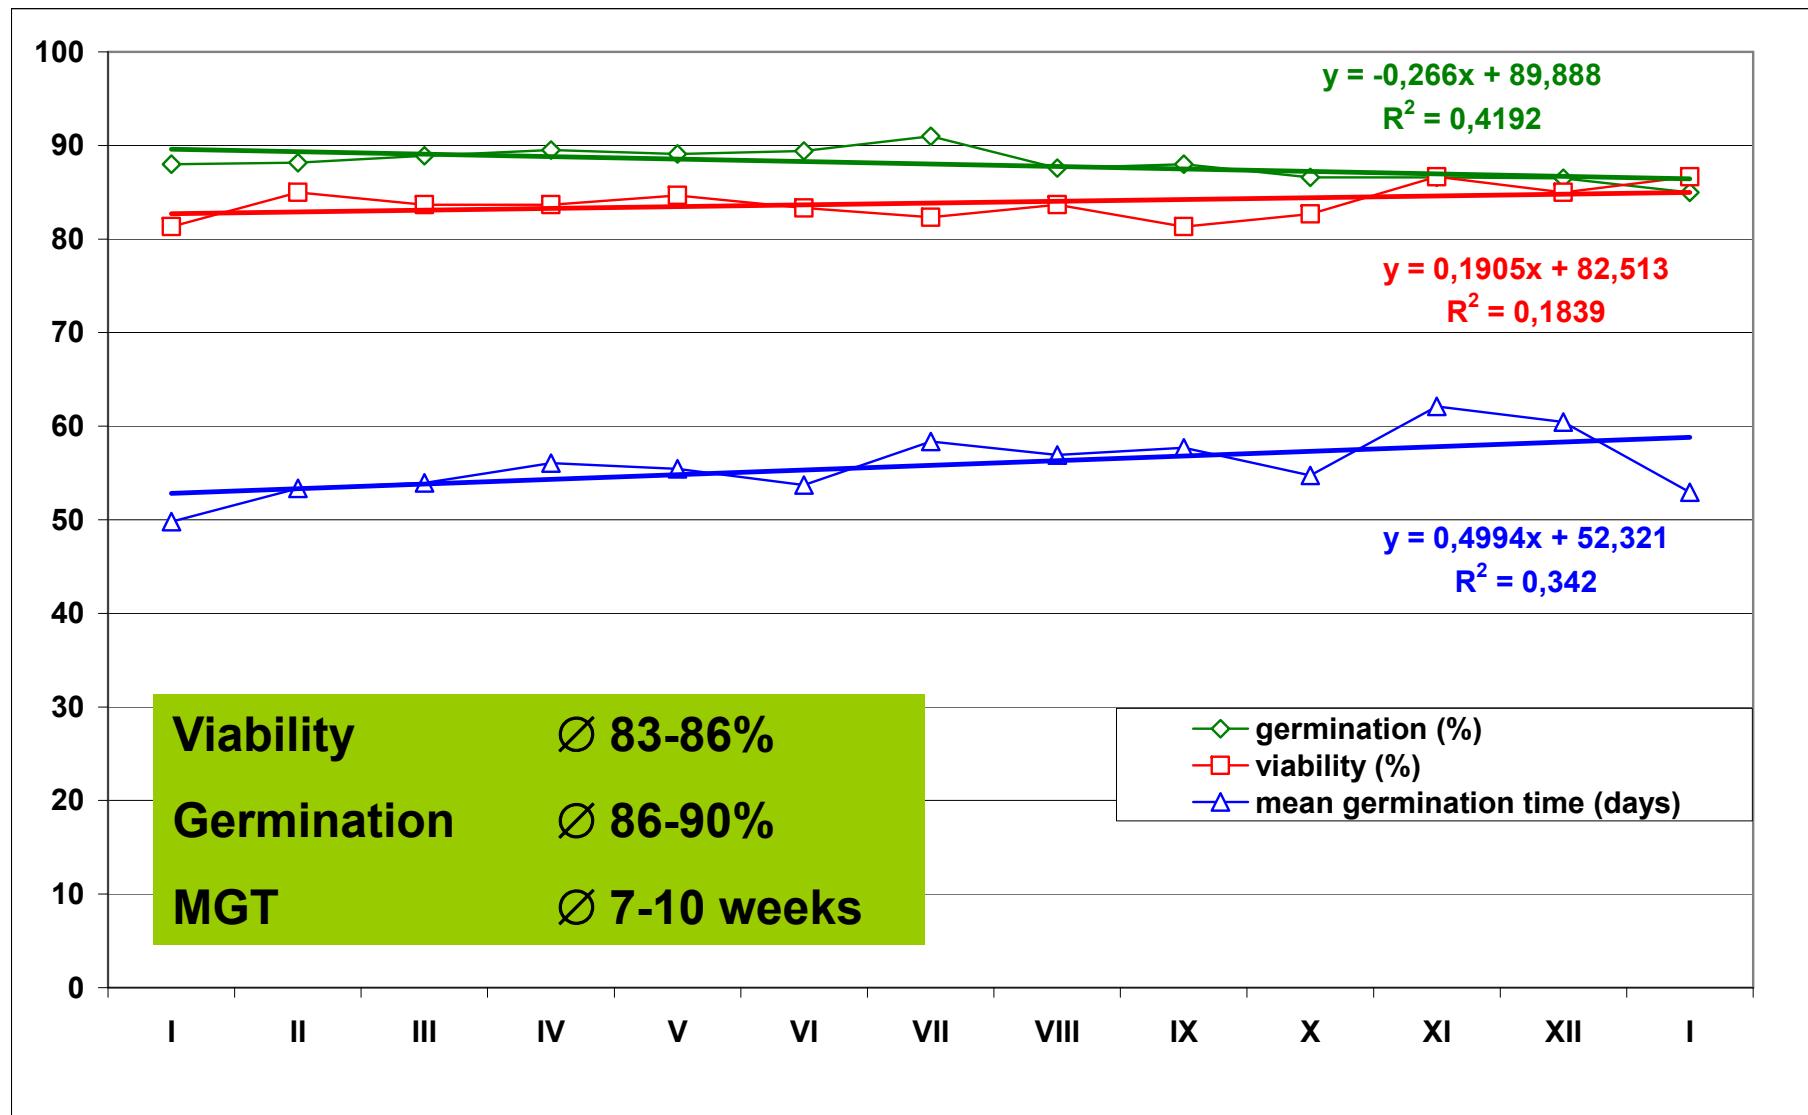

Seasonal changes in viability, germination capacity / rate

harvest 2009

Seasonal changes in viability, germination capacity / rate

harvest 2010

Conclusion

No consistent seasonal fluctuation in germination, germination rate and viability of the beechnuts was observed in the tests

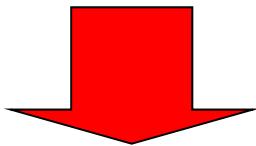

There were determined differences in germination, speed of germination and viability of stored dormant beech seeds done monthly

Among important factors that might influence the reliability of the repeated test seem to be initial seed quality (namely germination and dormancy)

Effect of harvest area size and locality on beechnut (*Fagus sylvatica*) germination: early results

Objective

Determine the effect of harvest area size and locality on germination (capacity and rate) of beechnuts

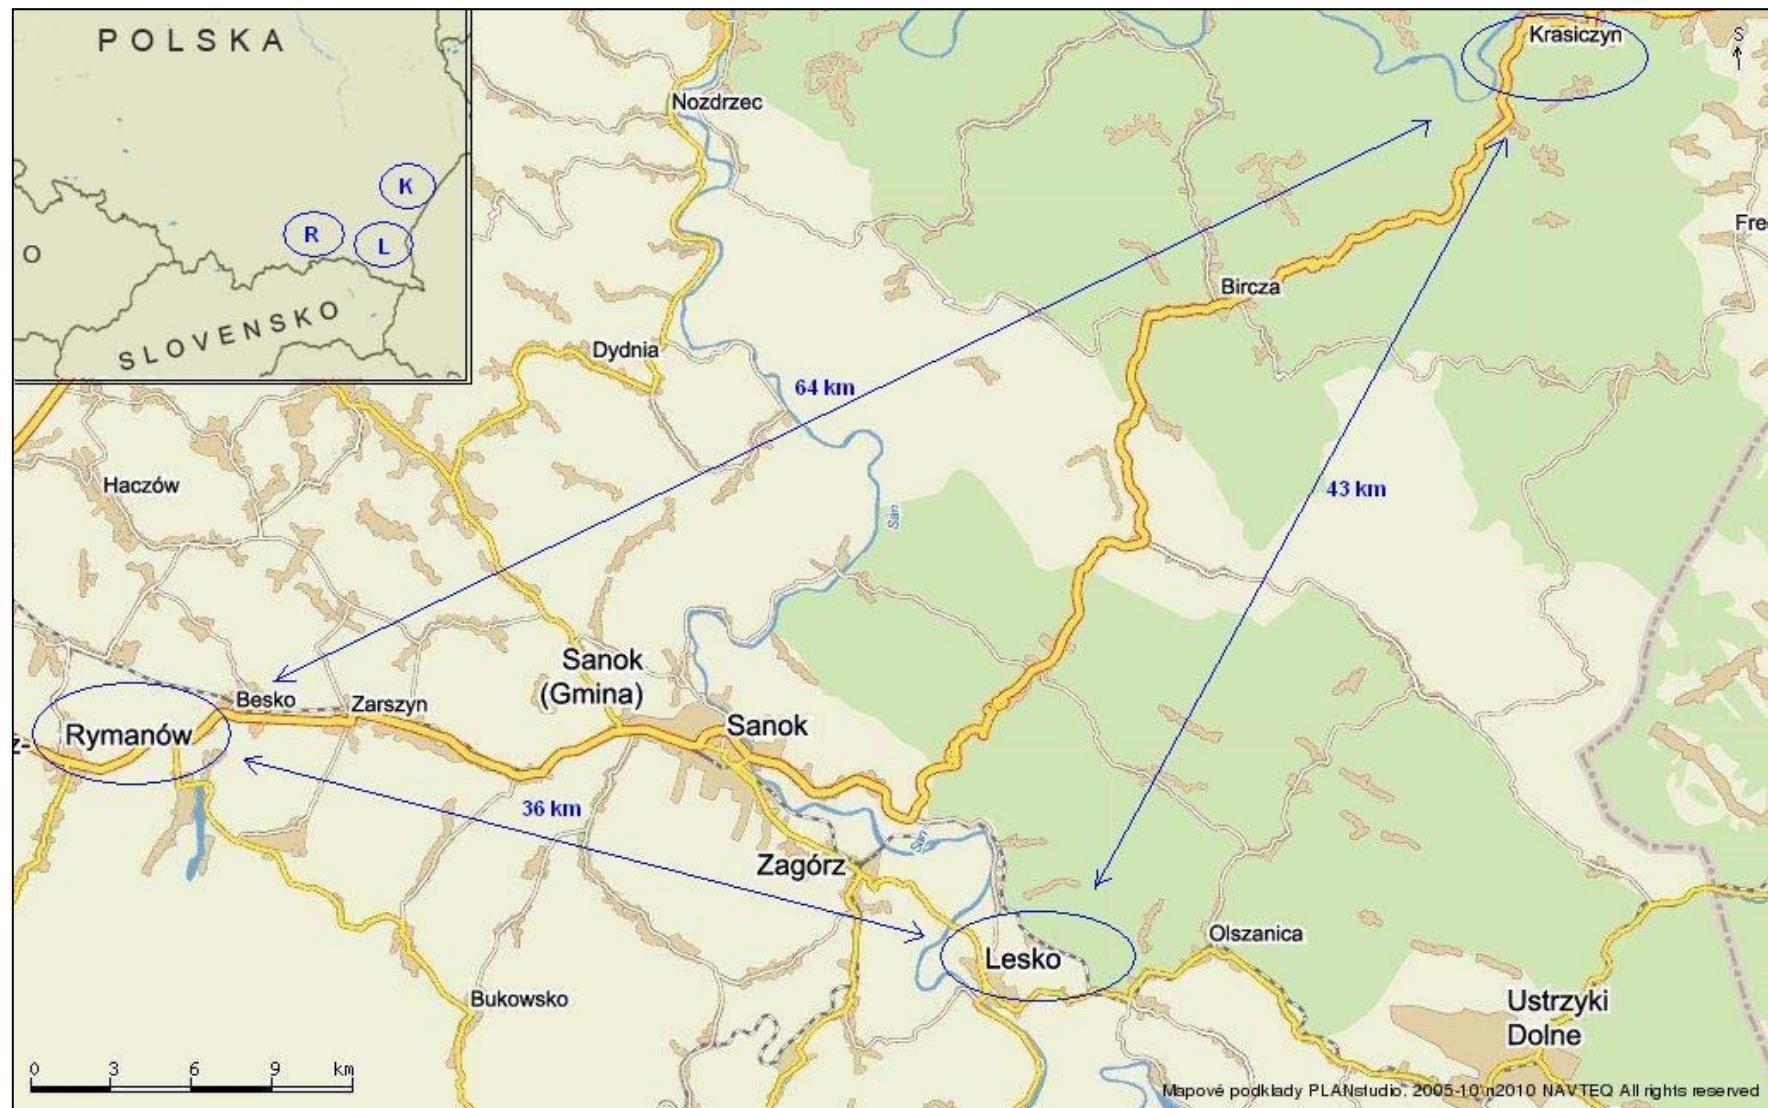

Evaluate the relation between dormancy and germination of beechnuts collected in stands with different climate conditions that are located within the same unit of approval (UA)

Material and methods

Collection 2010

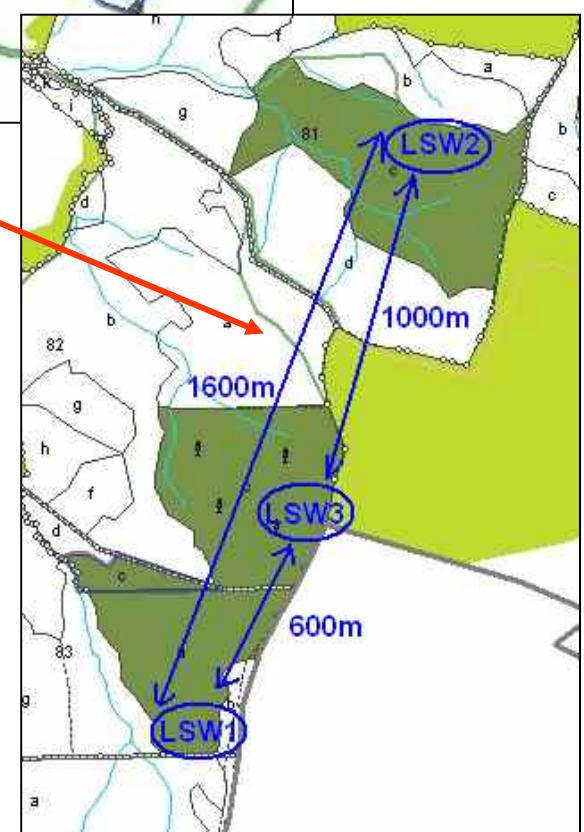

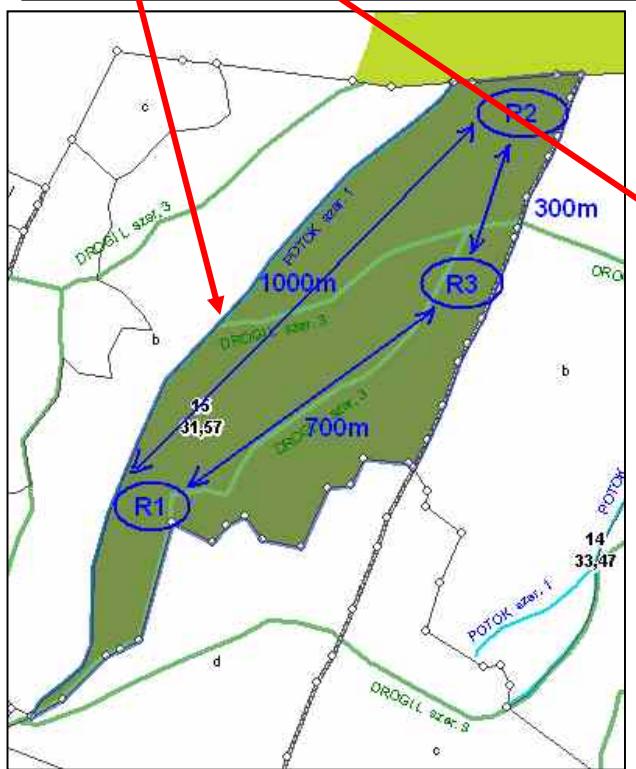

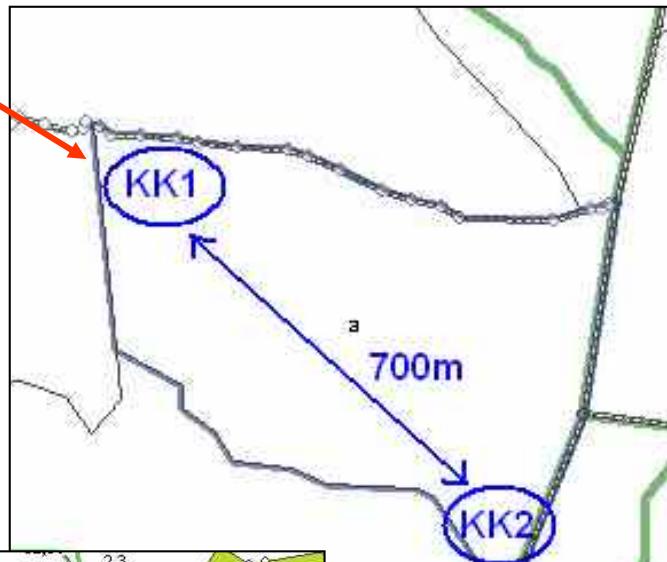

early October to early November

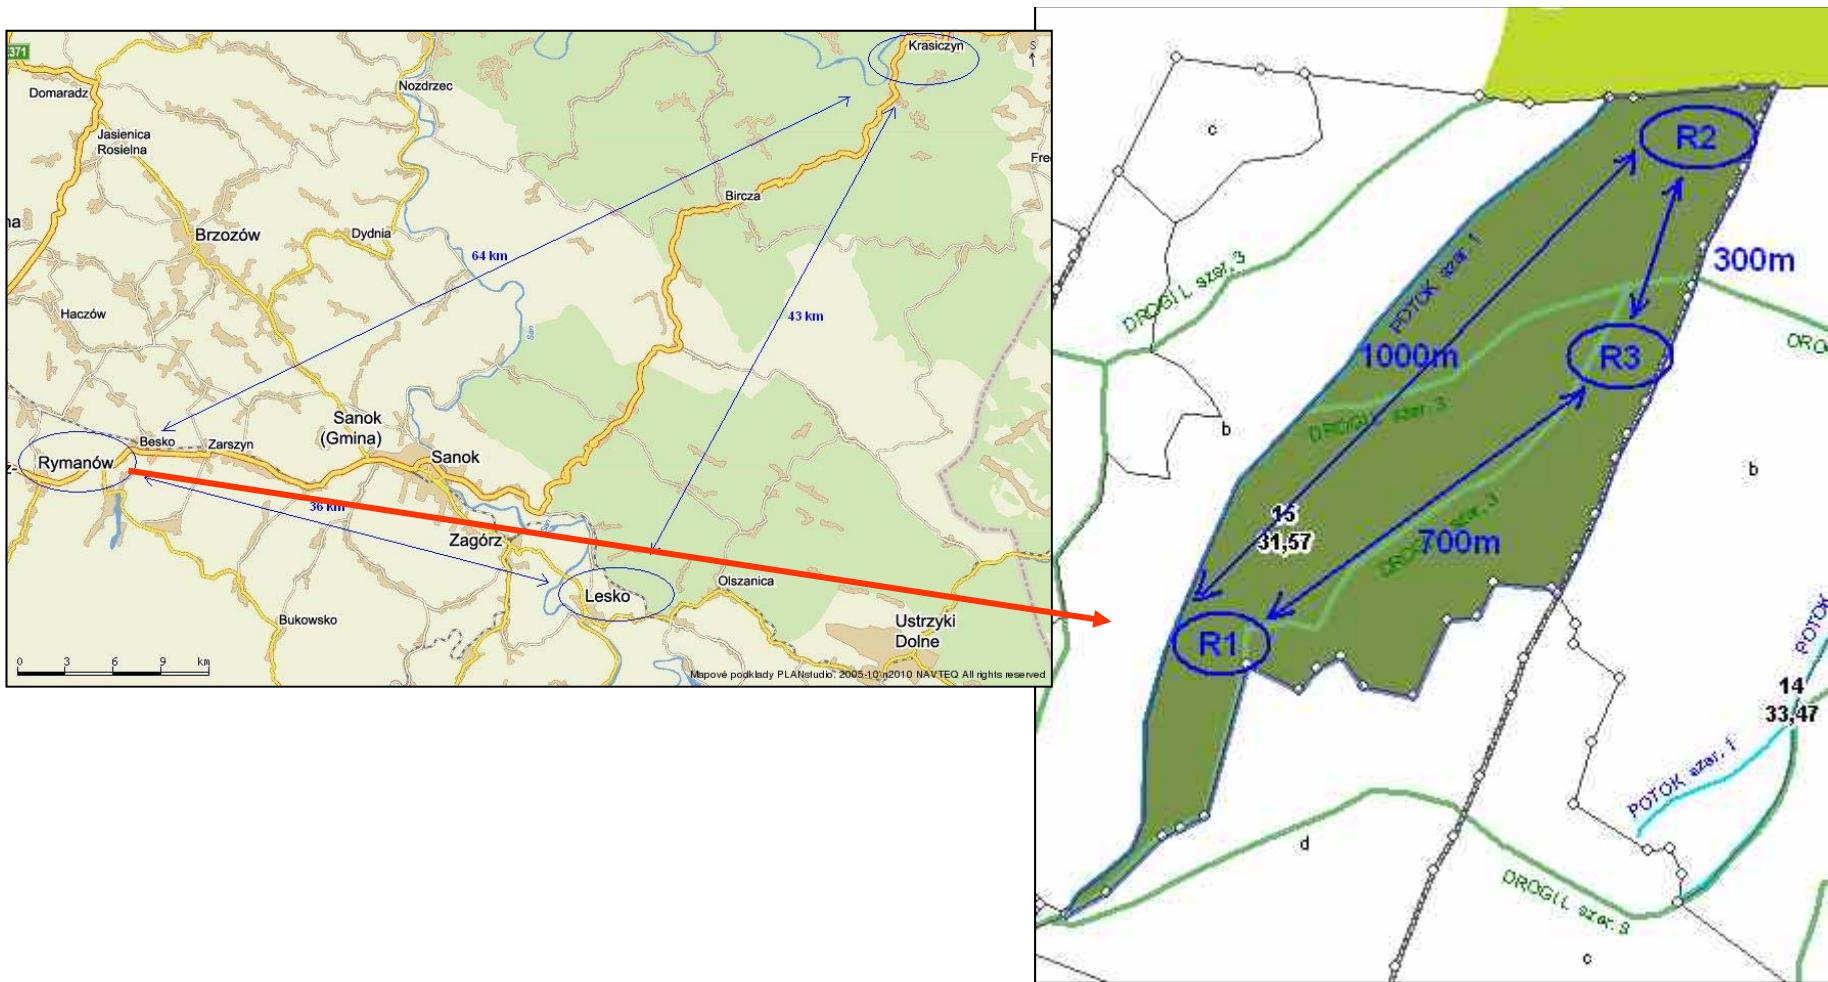

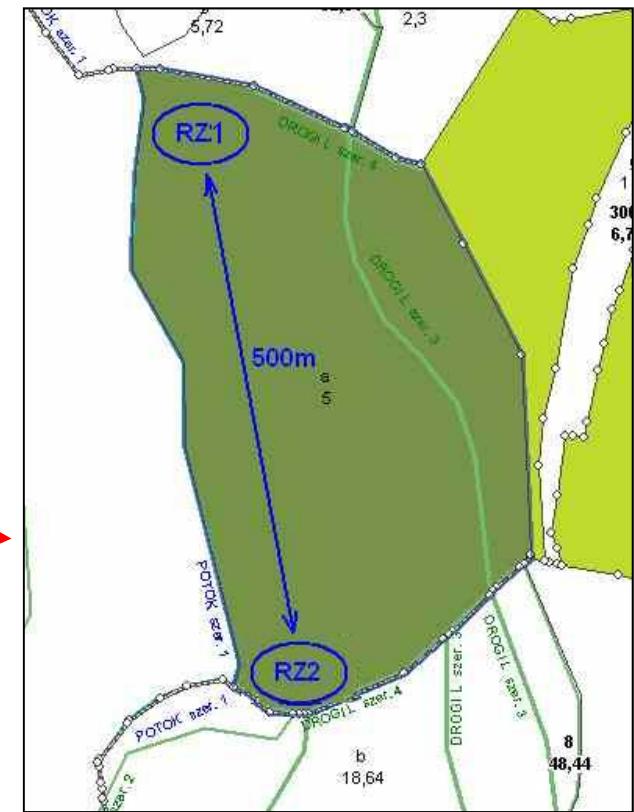

early September 2010

	Area (ha)	Exposition	Age (years)	Altitude (m a. s.)	Harvest

Results harvest 2011

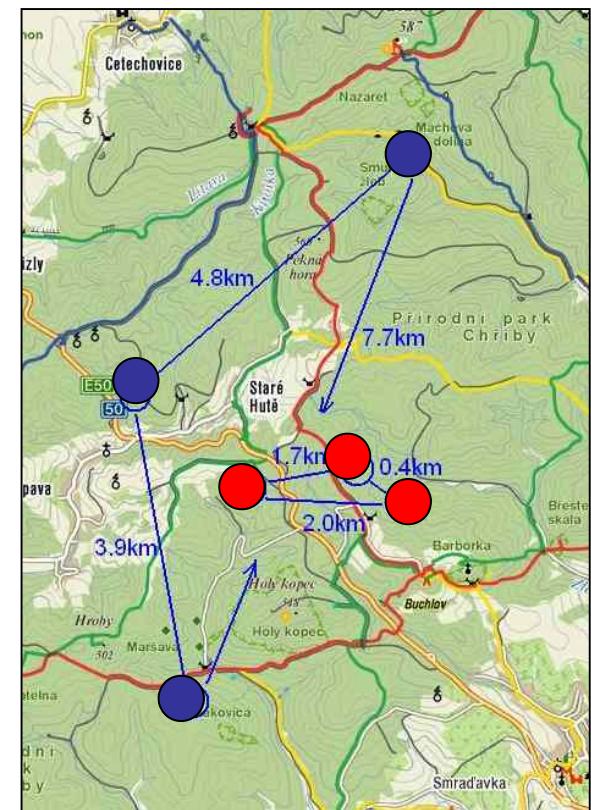

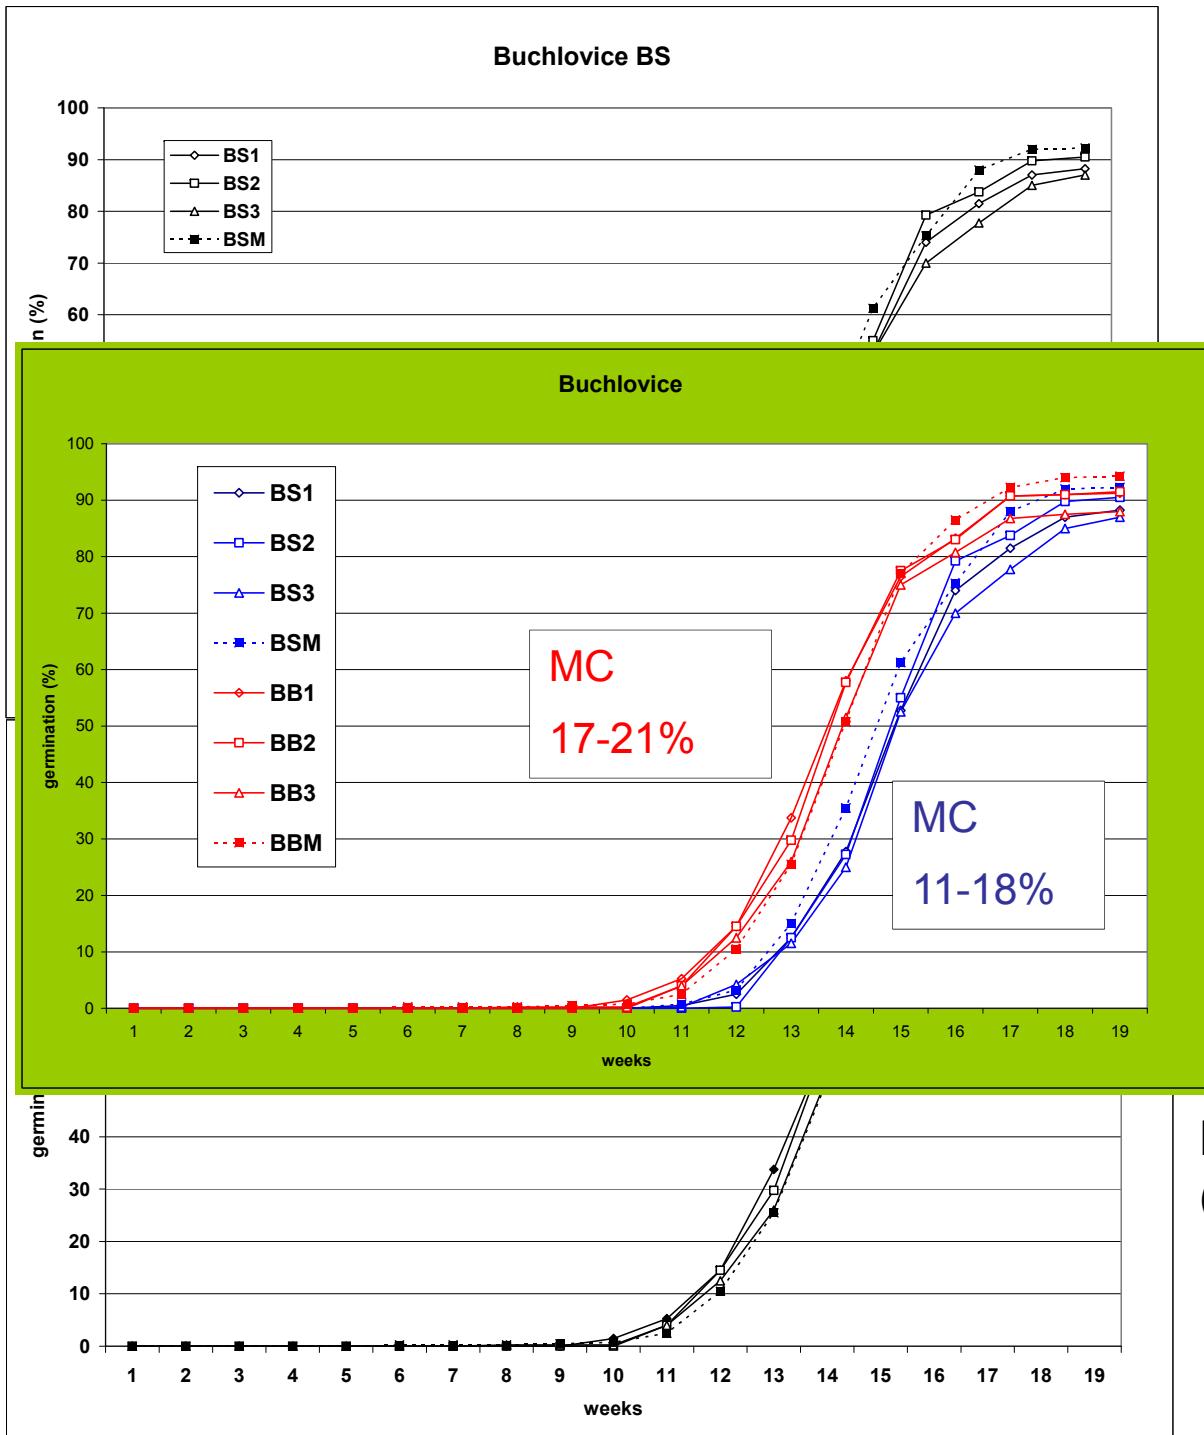

Germination

BS1-3 90 – 91%

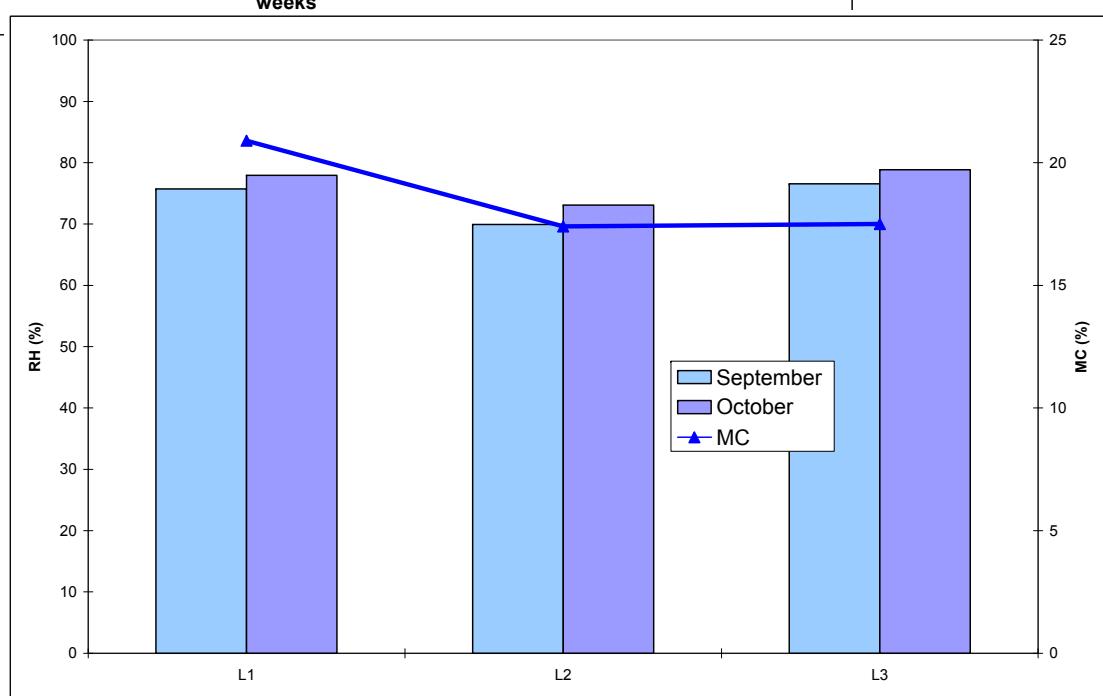

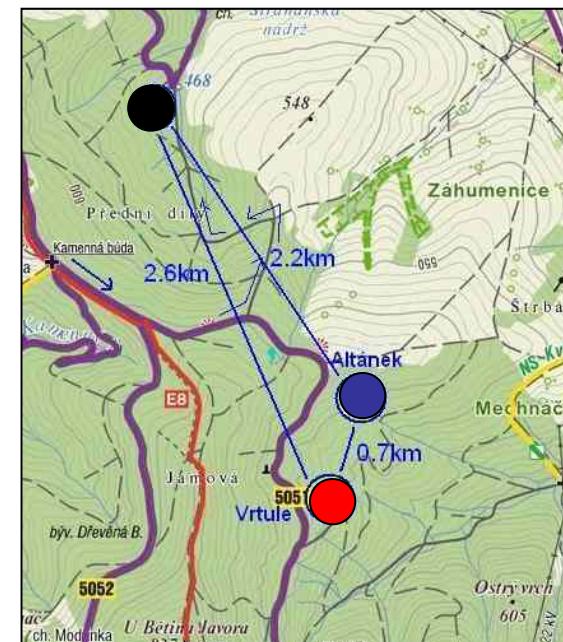

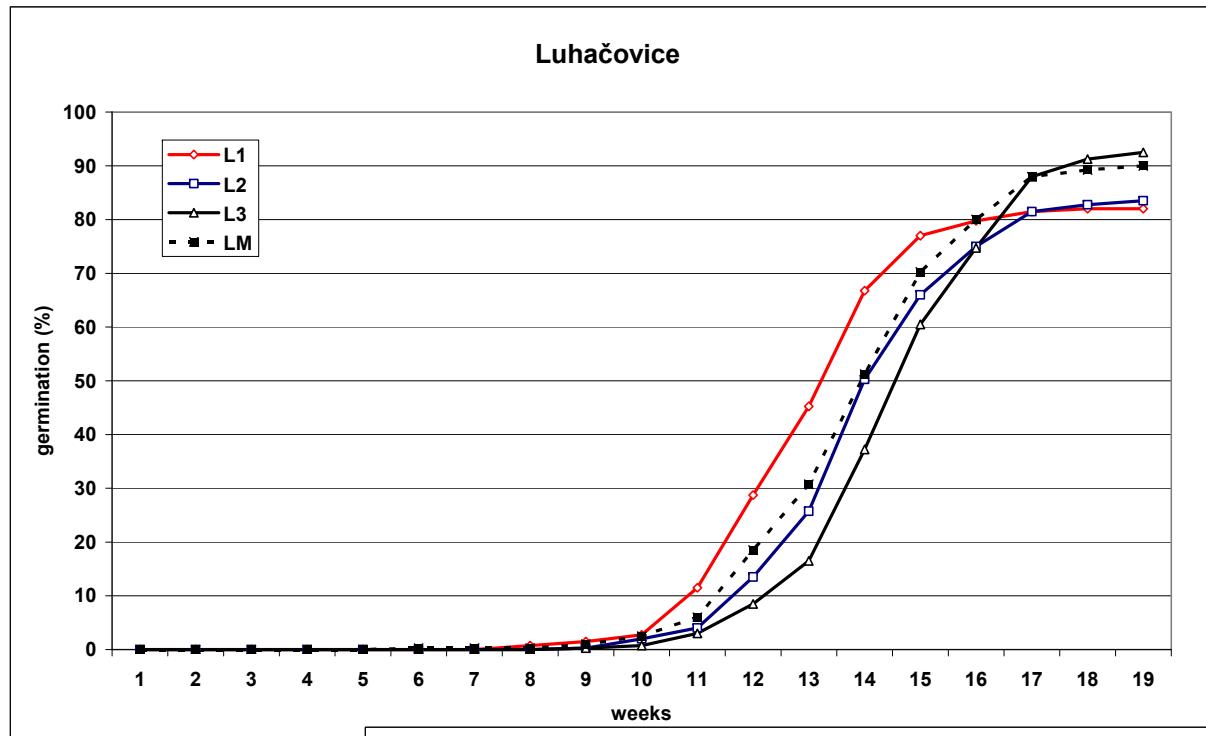

BSM 93%

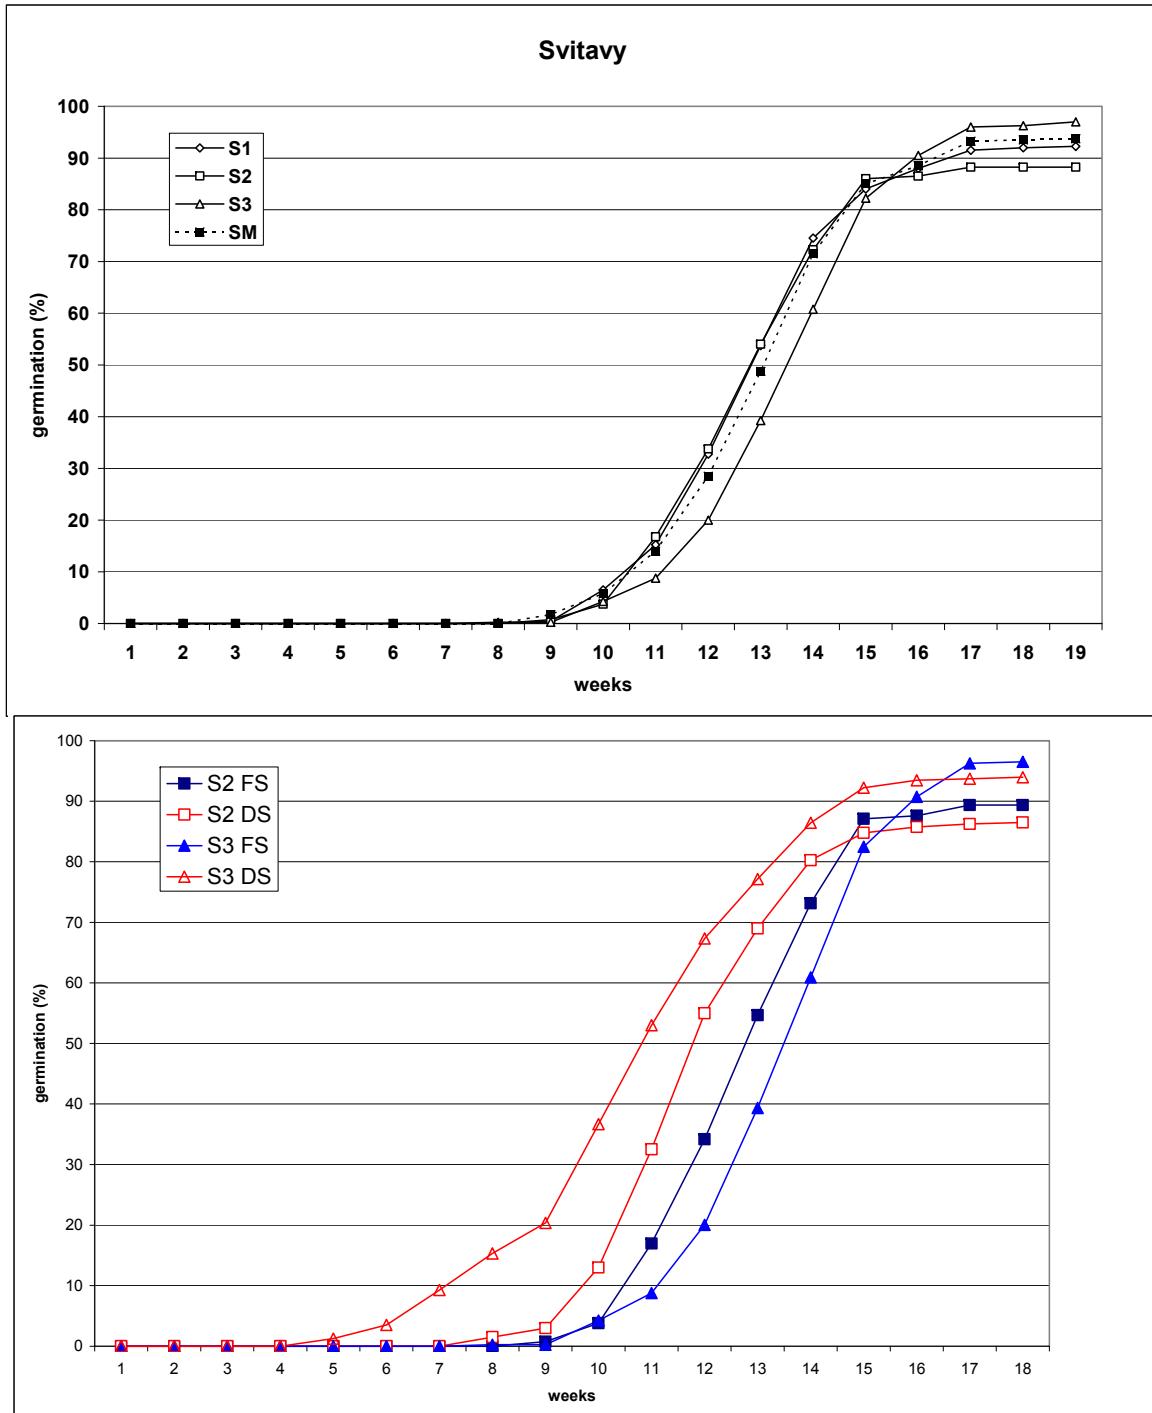

BB 1-3 90 – 92%

BBM 95%

Different speed of germination
(dormancy release)

Dried seeds germinate earlier than Fresh seeds

Conclusions

Beechnuts collected from different harvest sites within large areas (UA) can

- reached significantly different germination
- show different levels of dormancy expressed by different speed of germination

Germination capacity and germination speed of mixed samples can differ from the original sub-lots

Beechnut seed lots collected from a large area can show high heterogeneity in germination and dormancy, and this can significantly affect uniformity of pre-sowing treatment and emergence in nurseries

Špačková

Anatomical structure of dormant beechnuts after harvest

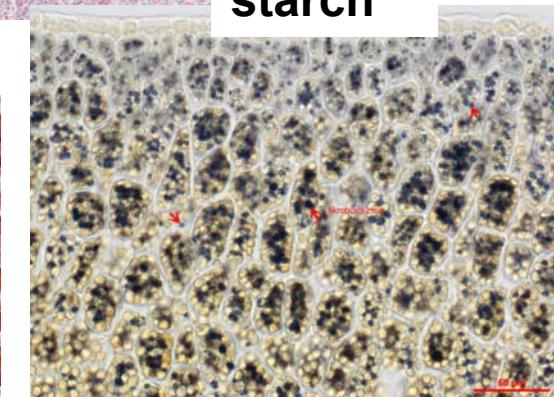

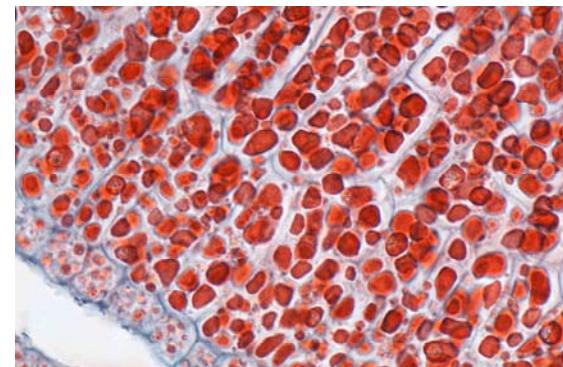

No significant difference in structure of dormant beechnuts from different seed lots

Cotyledons contain storage matters (starch, proteins, fat corpuscles, calcium oxalate crystals)

starch

Vacuoles with storage proteins

ABA and IAA in dormant and non dormant beechnuts

3 seed lots

Dormant seeds

Non Dormant seeds

MC 10%

3 x 10 seeds

embryonic axis (EA)  2% of whole embryo (E)
cotyledons (C)  98% of whole embryo (E)

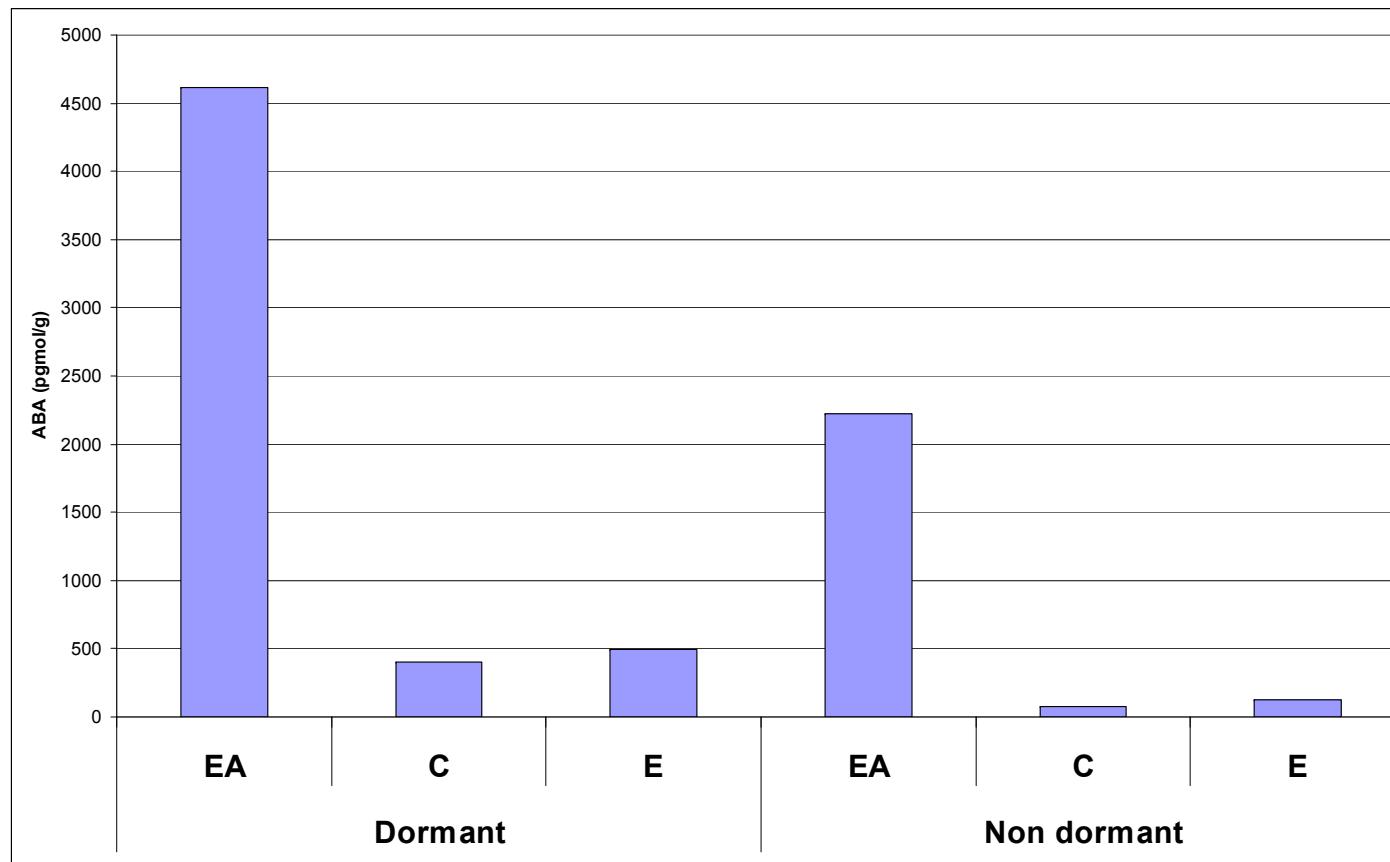

ABA in dormant and non dormant beechnuts

Significant differences between Dormant x Non Dormant seeds

embryonic axis (EA) 2,000 - 6,000 pmol.g⁻¹

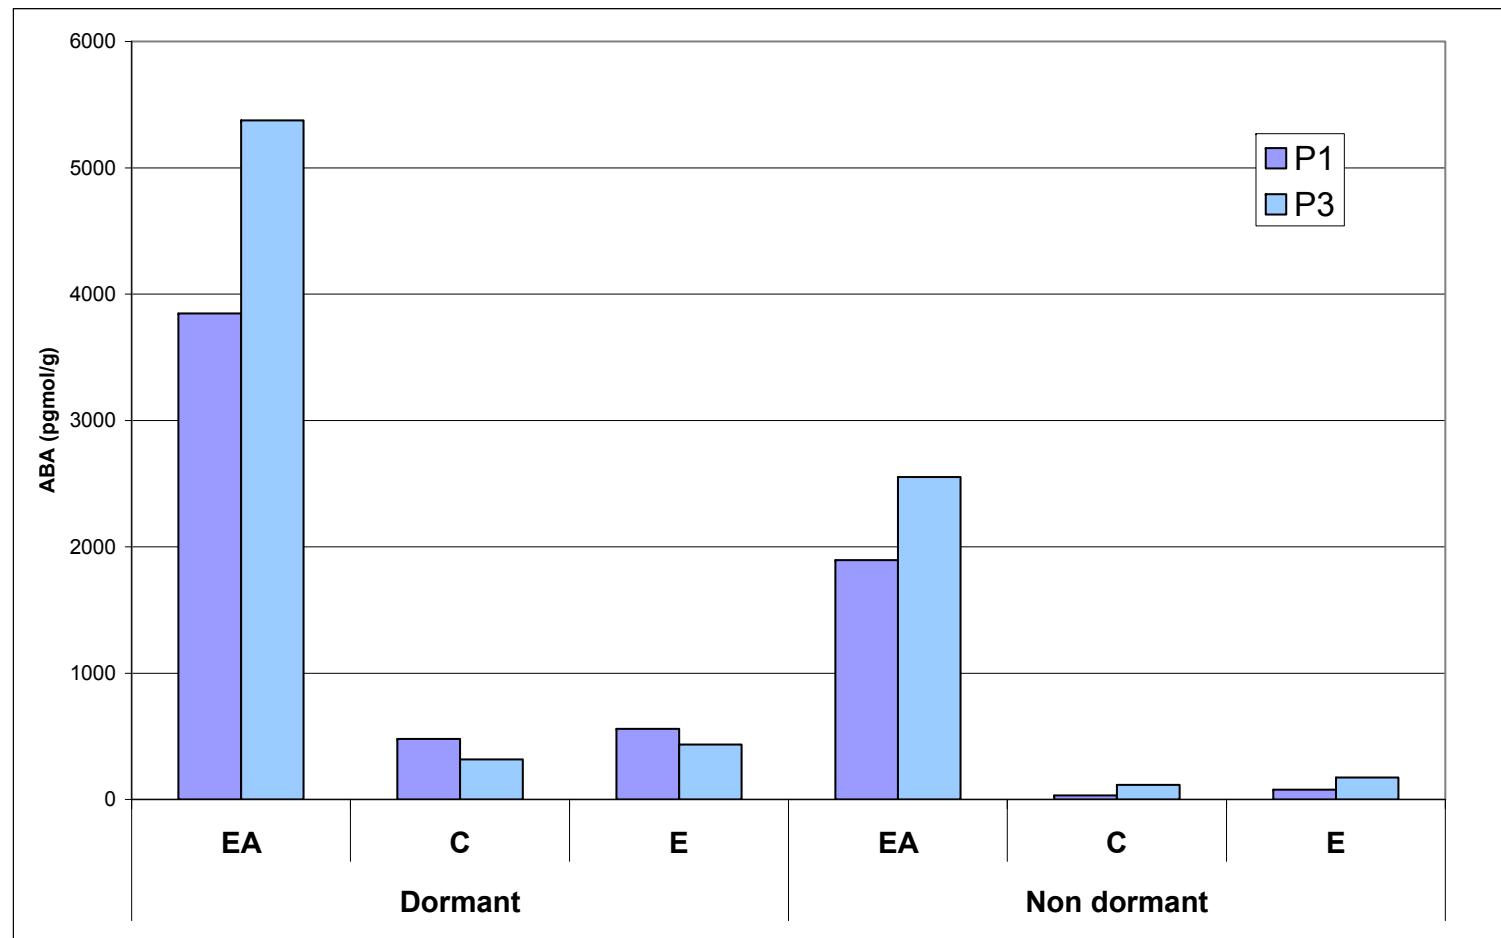

cotyledons (C) < 1,000 pmol.g⁻¹

whole embryo (E) < 1,000 pmol.g⁻¹

ABA in dormant and non dormant beechnuts

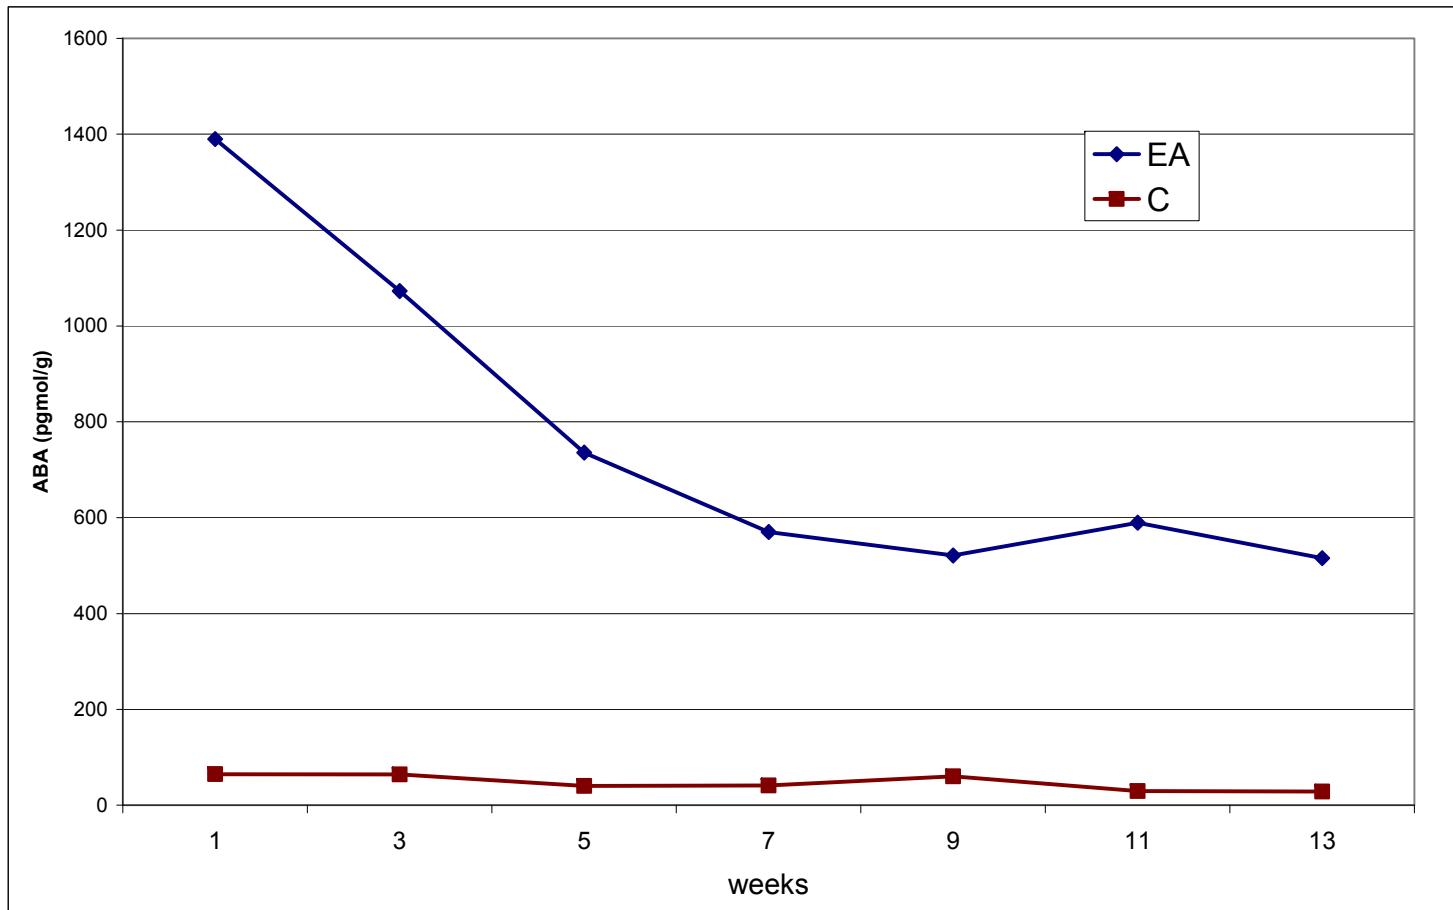

Differences between seed lots

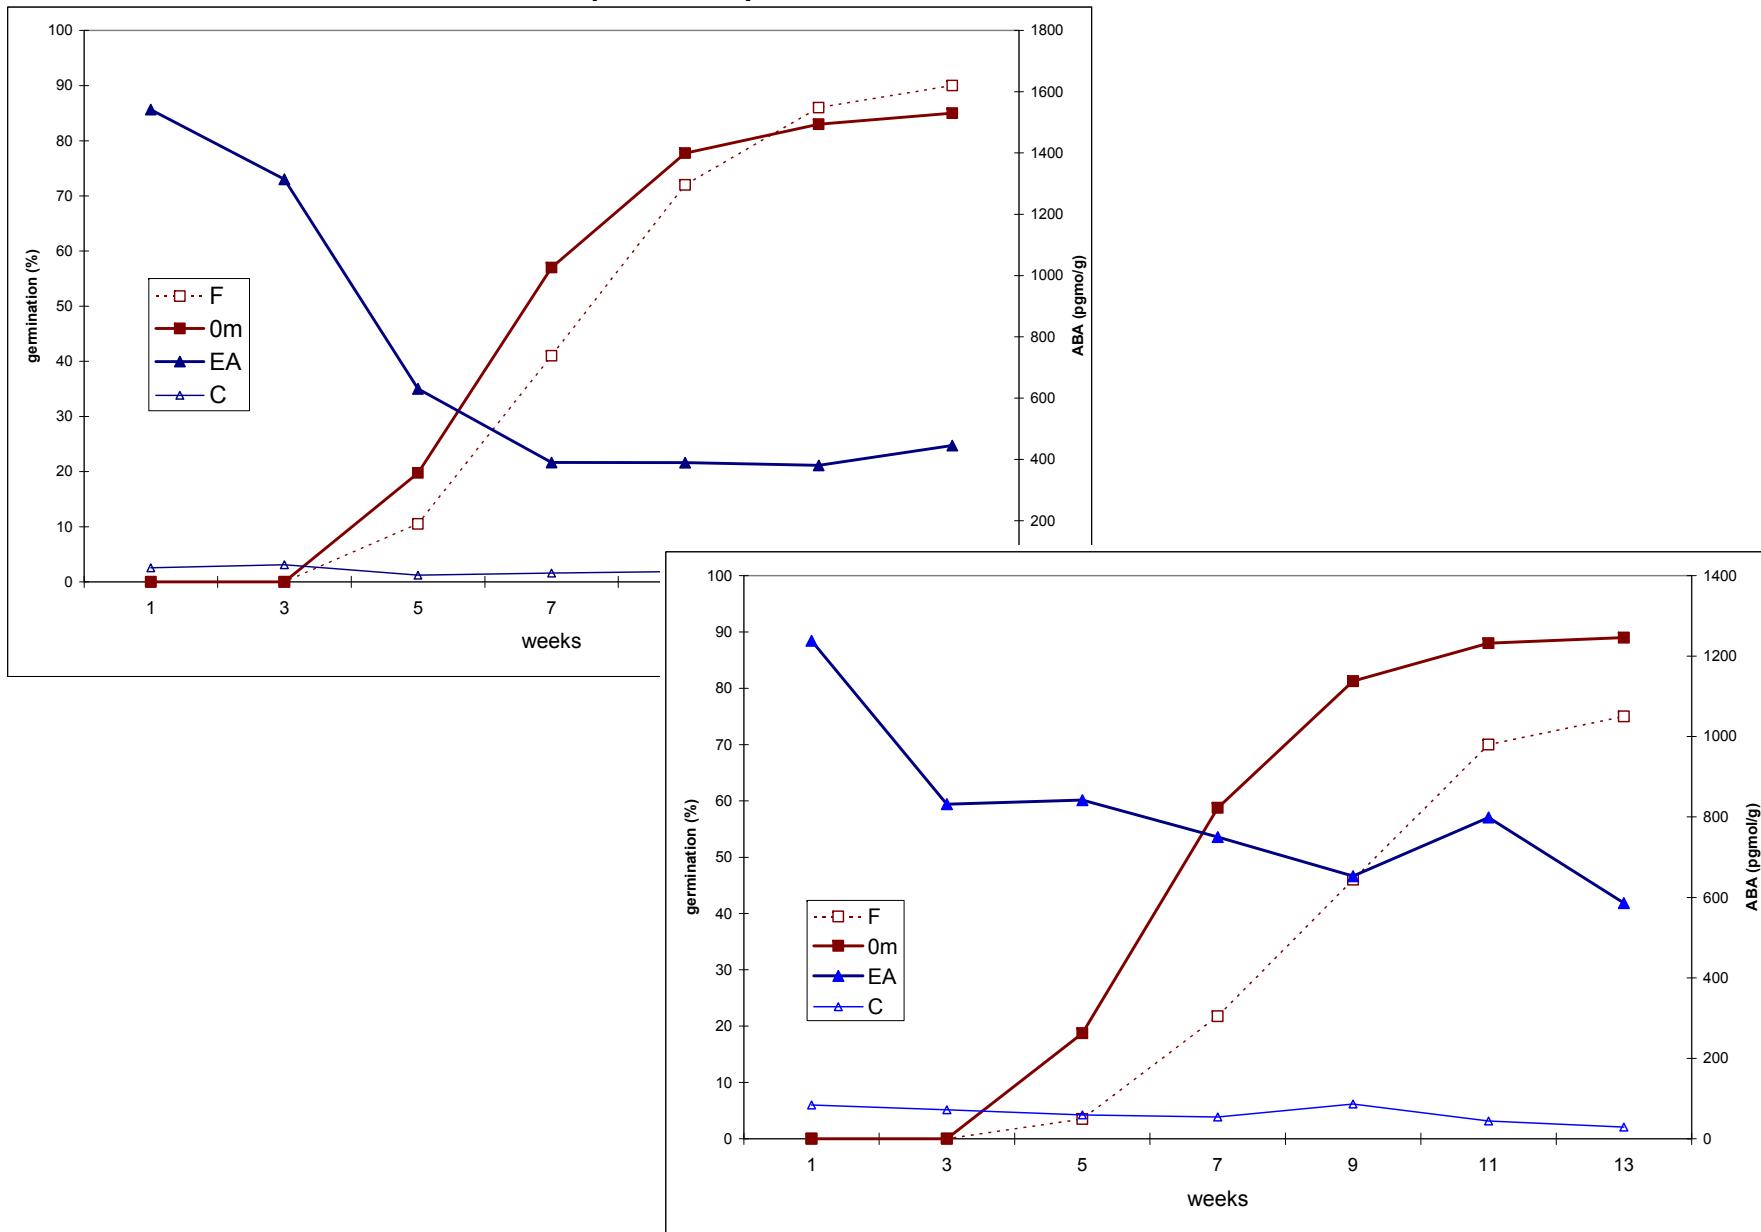

ABA in beechnuts during stratification

MC 28%

After 13 weeks ABA content declined to half of original content

ABA in beechnuts during stratification. Endogenic ABA correlates with dormancy during stratification

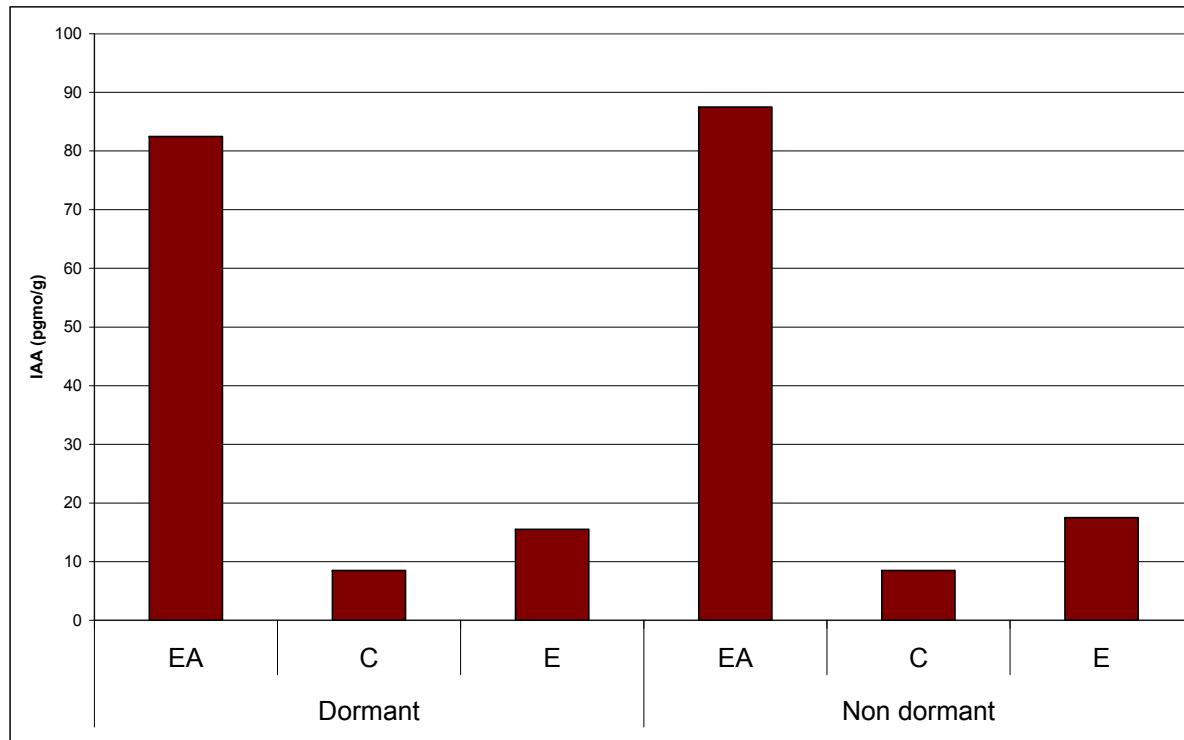

IAA in dormant and non dormant beechnuts

No significant differences between Dormant and Non Dormant seeds

embryonic axis (EA) about 100 pmol.g⁻¹

cotyledons (C) < 20 pmol.g⁻¹

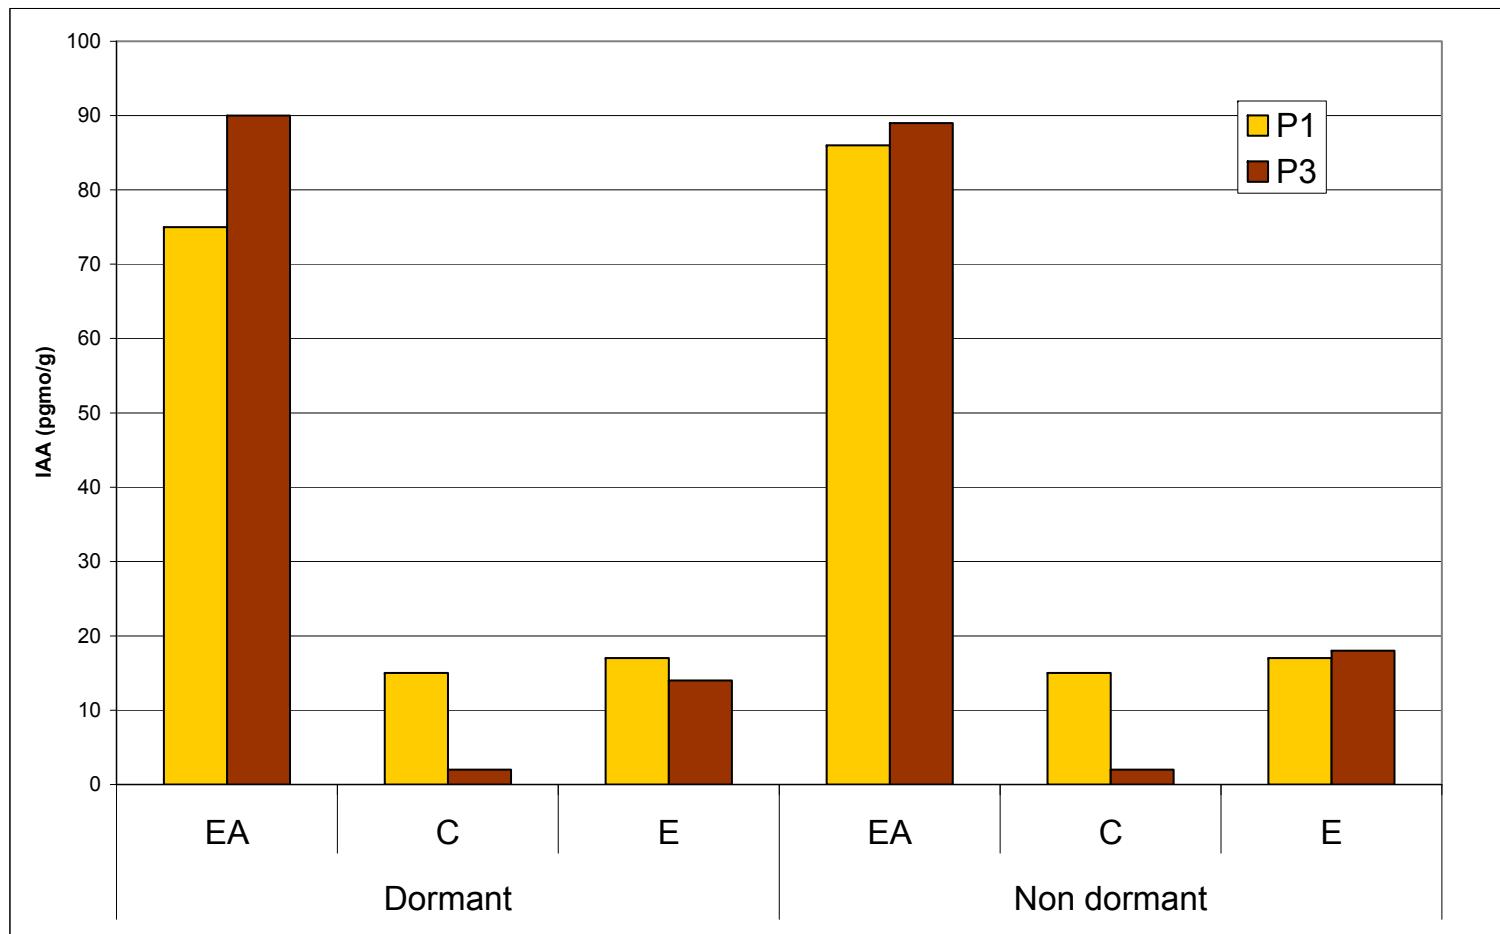

whole embryo (E) < 20 pmol.g⁻¹

IAA in dormant and non dormant beechnuts

No significant differences between seed lots

Endogenic IAA likely does not correlates with dormancy
